Library B_Unification.intro

1.1 Introduction

1.2 Unification

Before defining what unification is, there is some terminology to understand. A *term* is either a variable or a function applied to terms [1]. By this definition, a constant term is just a nullary function. A *variable* is a symbol capable of taking on the value of any term. An example of a term is $f(a, x)$, where f is a function of two arguments, a is a constant, and x is a variable. A term is *ground* if no variables occur in it [2]. The last example is not a ground term but $f(a, a)$ would be.

A *substitution* is a mapping from variables to terms. The *domain* of a substitution is the set of variables that do not get mapped to themselves. The *range* is the set of terms they are mapped to by the domain [2]. It is common for substitutions to be referred to as mappings from terms to terms. A substitution σ can be extended to this form by defining $\hat{\sigma}(s)$ for two cases of s . If s is a variable, then $\hat{\sigma}(s) := \sigma(s)$. If s is a function $f(s_1, \dots, s_n)$, then $\hat{\sigma}(s) := f(\hat{\sigma}(s_1), \dots, \hat{\sigma}(s_n))$ [3].

Unification is the process of solving a set of equations between two terms. The set of equations is referred to as a *unification problem* [4]. The process of solving one of these problems can be classified by the set of terms considered and the equality of any two terms. The latter property is what distinguishes two broad groups of algorithms, namely syntactic and semantic unification. If two terms are only considered equal if they are identical, then the unification is *syntactic* [4]. If two terms are equal with respect to an equational theory, then the unification is *semantic* [5].

The goal of unification is to solve a problem, which means to produce a substitution that unifies all equations of a problem. A substitution σ *unifies* an equation $s \stackrel{?}{=} t$ if applying σ to both sides makes them equal $\sigma(s) = \sigma(t)$. If σ unifies every equation in the problem S , we call σ a *solution* or *unifier* of S [4].

The goal of a unification algorithm is not just to produce a unifier but to produce one that is most general. A substitution is a *most general unifier* or *mgu* of a problem if it is

more general than every other solution to the problem. A substitution σ is *more general* than σ' if there exists a third substitution δ such that $\sigma'(u) = \delta(\sigma(u))$ for any term u [4].

1.2.1 Syntactic Unification

This is the simpler version of unification. For two terms to be considered equal they must be identical. For example, the terms $x * y$ and $y * x$ are not syntactically equal, but would be equal modulo commutativity of multiplication. Problems of this kind can be solved by repeated transformations until the solution pops out similar to solving a linear system by Gaussian elimination [6]. This version of unification is considered a simpler version of semantic unification because it is the special case where the set of equational identities is empty.

1.2.2 Semantic Unification

This kind of unification involves an equational theory. Given a set of identities E , we write that two terms s and t are equal with regards to E as $s \approx_E t$. This means that identities of E can be applied to s as s' and t as t' in some way to make them syntactically equal, $s' = t'$. As an example, let C be the set $\{f(x, y) \approx f(y, x)\}$. This theory axiomatizes the commutativity of the function f . Knowing this, the problem $\{f(x, a) \stackrel{?}{=} f(a, b)\}$ is unified by the substitution $\{x \mapsto b\}$ since $f(b, a) \approx_C f(a, b)$. In general, for an arbitrary E , the problem of E -unification is undecidable [4].

1.2.3 Boolean Unification

In this paper, we focus on unification modulo Boolean ring theory, also referred to as B -unification. The allowed terms in this theory are the constants 0 and 1 and binary functions $+$ and $*$. The set of identities B is defined as the set $\{x + y \approx y + x, (x + y) + z \approx x + (y + z), x + x \approx 0, 0 + x \approx x, x * (y + z) \approx (x * y) + (x * z), x * y \approx y * x, (x * y) * z \approx x * (y * z), x * x \approx x, 0 * x \approx 0, 1 * x \approx x\}$ [7]. This set is equivalent to the theory of real numbers with the addition of $x + x \approx_B 0$ and $x * x \approx_B x$.

Although a unification problem is a set of equations between two terms, we will now show informally that a B -unification problem can be viewed as a single equation $t \stackrel{?}{\approx}_B 0$. Given a problem in its normal form $\{s_1 \stackrel{?}{\approx}_B t_1, \dots, s_n \stackrel{?}{\approx}_B t_n\}$, we can transform it into $\{s_1 + t_1 \stackrel{?}{\approx}_B 0, \dots, s_n + t_n \stackrel{?}{\approx}_B 0\}$ using a simple fact. The equation $s \approx_B t$ is equivalent to $s + t \approx_B 0$ since adding t to both sides of the equation turns the right hand side into $t + t$ which simplifies to 0. Then, given a problem $\{t_1 \stackrel{?}{\approx}_B 0, \dots, t_n \stackrel{?}{\approx}_B 0\}$, we can transform it into $\{(t_1 + 1) * \dots * (t_n + 1) \stackrel{?}{\approx}_B 1\}$. Unifying both of these sets is equivalent because if any t_1, \dots, t_n is 1 the problem is not unifiable. Otherwise, if every t_1, \dots, t_n can be made to equal 0, then both problems will be solved.

1.3 Formal Verification

Formal verification is the term used to describe the act of verifying (or disproving) the correctness of software and hardware systems or theories. Formal verification consists of a set of techniques that perform static analysis on the behavior of a system, or the correctness of a theory. It differs to dynamic analysis that uses simulation to evaluate the correctness of a system.

Formal verification is used because it does not have to evaluate every possible case or state to determine if a system or theory meets all the preset logical conditions and requirements. Moreover, as design and software systems sizes have increased (along with their simulation times), verification teams have been looking for alternative methods of proving or disproving the correctness of a system in order to reduce the required time to perform a correctness check or evaluation.

1.3.1 Proof Assistance

A proof assistant is a software tool that is used to formulate and prove or disprove theorems in computer science or mathematical logic. They are also be called interactive theorem provers and they may also involve some type of proof and text editor that the user can use to form and prove and define theorems, lemmas, functions, etc. They facilitate that process by allowing the user to search definitions, terms and even provide some kind of guidance during the formulation or proof of a theorem.

1.3.2 Verifying Systems

1.3.3 Verifying Theories

1.4 Importance

1.5 Development

There are many different approaches that one could take to go about formalizing a proof of Boolean Unification algorithms, each with their own challenges. For this development, we have opted to base our work largely off chapter 10, *Equational Unification*, in *Term Rewriting and All That* by Franz Baader and Tobias Nipkow. Specifically, section 10.4, titled *Boolean Unification*, details Boolean rings, data structures to represent them, and two algorithms to perform unification in Boolean rings.

We chose to implement two data structures for representing the terms of a Boolean unification problem, and two algorithms for performing unification. The two data structures chosen are an inductive Term type and lists of lists representing polynomial-form terms. The two algorithms are Lowenheim's formula and successive variable elimination.

1.5.1 Data Structures

The data structure used to represent a Boolean unification problem completely changes the shape of both the unification algorithm and the proof of correctness, and is therefore a very important decision. For this development, we have selected two different representations of Boolean rings \u2013 first as a \u201cTerm\u201d inductive type, and then as lists of lists representing terms in polynomial form.

The Term inductive type, used in the proof of Lowenheim\u2019s algorithm, is very simple and rather intuitive \u2013 a term in a Boolean ring is one of 5 things:

- The number 0
- The number 1
- A variable
- Two terms added together
- Two terms multiplied together

In our development, variables are represented as natural numbers.

After defining terms like this, it is necessary to define a new equality relation, referred to as term equivalence, for comparing terms. With the term equivalence relation defined, it is easy to define ten axioms enabling the ten identities that hold true over terms in Boolean rings.

The inductive representation of terms in a Boolean ring is defined in the file *terms.v*. Unification over these terms is defined in *term_unif.v*.

The second representation, used in the proof of successive variable elimination, uses lists of lists of variables to represent terms in polynomial form. A monomial is a list of distinct variables multiplied together. A polynomial, then, is a list of distinct monomials added together. Variables are represented the same way, as natural numbers. The terms 0 and 1 are represented as the empty polynomial and the polynomial containing only the empty monomial, respectively.

The interesting part of the polynomial representation is how the ten identities are implemented. Rather than writing axioms enabling these transformations, we chose to implement the addition and multiplication operations in such a way to ensure these rules hold true, as described in *Term Rewriting*.

Addition is performed by cancelling out all repeated occurrences of monomials in the result of appending the two lists together (ie, $x+x=0$). This is equivalent to the symmetric difference in set theory, keeping only the terms that are in either one list or the other (but not both). Multiplication is slightly more complicated. The product of two polynomials is the result of multiplying all combinations of monomials in the two polynomials and removing all repeated monomials. The product of two monomials is the result of keeping only one copy of each repeated variable after appending the two together.

By defining the functions like this, and maintaining that the lists are sorted with no duplicates, we ensure that all 10 rules hold over the standard coq equivalence function. This of course has its own benefits and drawbacks, but lent itself better to the nature of successive variable elimination.

The polynomial representation is defined in the file *poly.v*. Unification over these polynomials is defined in *poly_unif.v*.

1.5.2 Algorithms

For unification algorithms, we once again followed the work laid out in *Term Rewriting and All That* and implemented both Lowenheim's algorithm and successive variable elimination.

The first solution, Lowenheim's algorithm, is built on top of the term inductive type. Lowenheim's is based on the idea that the Lowenheim formula can take a ground unifier of a Boolean unification problem and turn it into a most general unifier. The algorithm then of course first requires finding a ground solution, accomplished through brute force, which is then passed through the formula to create a most general unifier. Lowenheim's algorithm is implemented in the file *lowenheim.v*, and the proof of correctness is in *lowenheim_proof.v*.

The second algorithm, successive variable elimination, is built on top of the list-of-list polynomial approach. Successive variable elimination is built on the idea that by factoring variables out of the equation one-by-one, we can eventually reach a ground unifier. This unifier can then be built up with the variables that were previously eliminated until a most general unifier for the original unification problem is achieved. Successive variable elimination and its proof of correctness are both in *sve.v*.

```

2.1 Introduction

In order for any proofs to be constructed in Coq, we need to formally define the logic and data across which said proofs will operate. Since the heart of our analysis is concerned with the unification of Boolean equations, it stands to reason that we should articulate precisely how algebra functions with respect to Boolean rings. To attain this, we shall formalize what an equation looks like, how it can be composed inductively, and also how substitutions behave when applied to equations.

2.2 Terms

2.2.1 Definitions

We shall now begin describing the rules of Boolean arithmetic as well as the nature of Boolean equations. For simplicity's sake, from now on we shall be referring to equations as terms.

Definition `var` := `nat`.

Definition `var_eq_dec` := `Nat.eq_dec`.

A term, as has already been previously described, is now inductively declared to hold either a constant value, a single variable, a sum of terms, or a product of terms.

Inductive `term`: Type :=

```

| T0 : term
| T1 : term
| VAR : var → term
| SUM : term → term → term
| PRODUCT : term → term → term.

```

For convenience's sake, we define some shorthanded notation for readability.

```
Implicit Types x y z : term.
```

```
Implicit Types n m : var.
```

```
Notation "x + y" := (SUM x y) (at level 50, left associativity).
```

```
Notation "x * y" := (PRODUCT x y) (at level 40, left associativity).
```

2.2.2 Axioms

Now that we have informed Coq on the nature of what a term is, it is now time to propose a set of axioms that will articulate exactly how algebra behaves across Boolean rings. This is a requirement since the very act of unifying an equation is intimately related to solving it algebraically. Each of the axioms proposed below describe the rules of Boolean algebra precisely and in an unambiguous manner. None of these should come as a surprise to the reader; however, if one is not familiar with this form of logic, the rules regarding the summation and multiplication of identical terms might pose as a source of confusion.

For reasons of keeping Coq's internal logic consistent, we roll our own custom equivalence relation as opposed to simply using '='. This will provide a surefire way to avoid any odd errors from later cropping up in our proofs. Of course, by doing this we introduce some implications that we will need to address later.

```
Parameter eqv : term → term → Prop.
```

```
Infix "==" := eqv (at level 70).
```

```
Axiom sum_comm : ∀ x y, x + y == y + x.
```

```
Axiom sum_assoc : ∀ x y z, (x + y) + z == x + (y + z).
```

```
Axiom sum_id : ∀ x, T0 + x == x.
```

```
Axiom sum_x_x : ∀ x, x + x == T0.
```

```
Axiom mul_comm : ∀ x y, x × y == y × x.
```

```
Axiom mul_assoc : ∀ x y z, (x × y) × z == x × (y × z).
```

```
Axiom mul_x_x : ∀ x, x × x == x.
```

```
Axiom mul_T0_x : ∀ x, T0 × x == T0.
```

```
Axiom mul_id : ∀ x, T1 × x == x.
```

```
Axiom distr : ∀ x y z, x × (y + z) == (x × y) + (x × z).
```

```
Axiom term_sum_symmetric :
```

```
  ∀ x y z, x == y ↔ x + z == y + z.
```

Axiom *term_product_symmetric* :
 $\forall x y z, x == y \leftrightarrow x \times z == y \times z.$

Axiom *refl_comm* :
 $\forall t1 t2, t1 == t2 \rightarrow t2 == t1.$

Axiom *T1_not_equiv_T0* :
 $\sim (T1 == T0).$

Hint Resolve *sum_comm sum_assoc sum_x_x sum_id distr*
mul_comm mul_assoc mul_x_x mul_T0_x mul_id.

Now that the core axioms have been taken care of, we need to handle the implications posed by our custom equivalence relation. Below we inform Coq of the behavior of our equivalence relation with respect to rewrites during proofs.

Axiom *eqv_ref* : **Reflexive** *eqv*.
Axiom *eqv_sym* : **Symmetric** *eqv*.
Axiom *eqv_trans* : **Transitive** *eqv*.

Add *Parametric Relation* : **term** *eqv*
reflexivity proved by @eqv_ref
symmetry proved by @eqv_sym
transitivity proved by @eqv_trans
as *eq_set_rel*.

Axiom *SUM_compat* :
 $\forall x x', x == x' \rightarrow$
 $\forall y y', y == y' \rightarrow$
 $(x + y) == (x' + y').$

Axiom *PRODUCT_compat* :
 $\forall x x', x == x' \rightarrow$
 $\forall y y', y == y' \rightarrow$
 $(x \times y) == (x' \times y').$

Add *Parametric Morphism* : **SUM** with
signature eqv ==> eqv ==> eqv as SUM_mor.

Proof.

exact *SUM_compat*.

Qed.

Add *Parametric Morphism* : **PRODUCT** with
signature eqv ==> eqv ==> eqv as PRODUCT_mor.

Proof.

exact *PRODUCT_compat*.

Qed.

Hint Resolve *eqv_ref eqv_sym eqv_trans SUM_compat PRODUCT_compat*.

2.2.3 Lemmas

Since Coq now understands the basics of Boolean algebra, it serves as a good exercise for us to generate some further rules using Coq's proving systems. By doing this, not only do we gain some additional tools that will become handy later down the road, but we also test whether our axioms are behaving as we would like them to.

Lemma `mul_x_x_plus_T1` :

$\forall x, x \times (x + T1) == T0.$

Proof.

`intros. rewrite distr. rewrite mul_x_x. rewrite mul_comm.`

`rewrite mul_id. apply sum_x_x.`

`Qed.`

Lemma `x_equal_y_x_plus_y` :

$\forall x\ y, x == y \leftrightarrow x + y == T0.$

Proof.

`intros. split.`

`- intros. rewrite H. rewrite sum_x_x. reflexivity.`

`- intros. rewrite term_sum_symmetric with $(y := y)\ (z := y)$. rewrite sum_x_x.
 apply H.`

`Qed.`

Hint Resolve `mul_x_x_plus_T1`.

Hint Resolve `x_equal_y_x_plus_y`.

These lemmas just serve to make certain rewrites regarding the core axioms less tedious to write. While one could certainly argue that they should be formulated as axioms and not lemmas due to their triviality, being pedantic is a good exercise.

Lemma `sum_id_sym` :

$\forall x, x + T0 == x.$

Proof.

`intros. rewrite sum_comm. apply sum_id.`

`Qed.`

Lemma `mul_id_sym` :

$\forall x, x \times T1 == x.$

Proof.

`intros. rewrite mul_comm. apply mul_id.`

`Qed.`

Lemma `mul_T0_x_sym` :

$\forall x, x \times T0 == T0.$

Proof.

`intros. rewrite mul_comm. apply mul_T0_x.`

`Qed.`

Lemma `sum_assoc_opp` :

```

 $\forall x\ y\ z, x + (y + z) == (x + y) + z.$ 
Proof.
  intros. rewrite sum_assoc. reflexivity.
Qed.

Lemma mul_assoc_opp :
 $\forall x\ y\ z, x \times (y \times z) == (x \times y) \times z.$ 
Proof.
  intros. rewrite mul_assoc. reflexivity.
Qed.

Lemma distr_opp :
 $\forall x\ y\ z, x \times y + x \times z == x \times (y + z).$ 
Proof.
  intros. rewrite distr. reflexivity.
Qed.

```

2.3 Variable Sets

Now that the underlying behavior concerning Boolean algebra has been properly articulated to Coq, it is now time to begin formalizing the logic surrounding our meta reasoning of Boolean equations and systems. While there are certainly several approaches to begin this process, we thought it best to ease into things through formalizing the notion of a set of variables present in an equation.

2.3.1 Definitions

We now define a variable set to be precisely a list of variables; additionally, we include several functions for including and excluding variables from these variable sets. Furthermore, since uniqueness is not a property guaranteed by Coq lists and it has the potential to be desirable, we define a function that consumes a variable set and removes duplicate entries from it. For convenience, we also provide several examples to demonstrate the functionalities of these new definitions.

```

Definition var_set := list var.
Implicit Type vars: var_set.

Fixpoint var_set_includes_var (v : var) (vars : var_set) : bool :=
  match vars with
  | nil  $\Rightarrow$  false
  | n :: n'  $\Rightarrow$  if (beq_nat v n) then true else var_set_includes_var v n'
  end.

Fixpoint var_set_remove_var (v : var) (vars : var_set) : var_set :=
  match vars with
  | nil  $\Rightarrow$  nil

```

```

|  $n :: n' \Rightarrow$  if (beq_nat  $v\ n$ ) then (var_set_remove_var  $v\ n'$ ) else  $n ::$  (var_set_remove_var
 $v\ n'$ )
end.

```

```

Fixpoint var_set_create_unique ( $vars : \text{var\_set}$ ):  $\text{var\_set} :=$ 
  match  $vars$  with
  | nil  $\Rightarrow$  nil
  |  $n :: n' \Rightarrow$ 
    if (var_set_includes_var  $n\ n'$ ) then var_set_create_unique  $n'$ 
    else  $n ::$  var_set_create_unique  $n'$ 
  end.

```

```

Fixpoint var_set_is_unique ( $vars : \text{var\_set}$ ): bool :=
  match  $vars$  with
  | nil  $\Rightarrow$  true
  |  $n :: n' \Rightarrow$ 
    if (var_set_includes_var  $n\ n'$ ) then false
    else var_set_is_unique  $n'$ 
  end.

```

```

Fixpoint term_vars ( $t : \text{term}$ ) :  $\text{var\_set} :=$ 
  match  $t$  with
  | T0  $\Rightarrow$  nil
  | T1  $\Rightarrow$  nil
  | VAR  $x \Rightarrow x ::$  nil
  | PRODUCT  $x\ y \Rightarrow$  (term_vars  $x$ ) ++ (term_vars  $y$ )
  | SUM  $x\ y \Rightarrow$  (term_vars  $x$ ) ++ (term_vars  $y$ )
  end.

```

```

Definition term_unique_vars ( $t : \text{term}$ ) :  $\text{var\_set} :=$ 
  (var_set_create_unique (term_vars  $t$ )).

```

```

Lemma vs_includes_true :  $\forall (x : \text{var}) (lvar : \text{list var}),$

        { simpl. left. apply H. }
        { specialize (IHlvar H). simpl. right. apply IHlvar. } }

```

Qed.

2.3.2 Examples

Example var_set_create_unique_ex1 :

var_set_create_unique [0;5;2;1;1;2;2;9;5;3] = [0;1;2;9;5;3].

Proof.

simpl. reflexivity.

Qed.

Example var_set_is_unique_ex1 :

var_set_is_unique [0;2;2;2] = false.

Proof.

simpl. reflexivity.

Qed.

Example term_vars_ex1 :

term_vars (VAR 0 + VAR 0 + VAR 1) = [0;0;1].

Proof.

simpl. reflexivity.

Qed.

Example term_vars_ex2 :

In 0 (term_vars (VAR 0 + VAR 0 + VAR 1)).

Proof.

simpl. left. reflexivity.

Qed.

2.4 Ground Terms

Seeing as we just outlined the definition of a variable set, it seems fair to now formalize the definition of a ground term, or in other words, a term that has no variables and whose variable set is the empty set.

2.4.1 Definitions

A ground term is a recursively defined proposition that is only True if and only if no variable appears in it; otherwise it will be a False proposition and no longer a ground term.

Fixpoint ground_term (t : term) : Prop :=

match t with

| VAR x ⇒ False

| SUM x y ⇒ (ground_term x) ∧ (ground_term y)

| PRODUCT x y ⇒ (ground_term x) ∧ (ground_term y)

```

| _ => True
end.

```

2.4.2 Lemmas

Our first real lemma (shown below), articulates an important property of ground terms: all ground terms are equivalent to either 0 or 1. This curious property is a direct result of the fact that these terms possess no variables and additionally because of the axioms of Boolean algebra.

Lemma `ground_term_equiv_T0_T1` :

$\forall x, (\text{ground_term } x) \rightarrow (x == T0 \vee x == T1).$

Proof.

`intros. induction x.`

`- left. reflexivity.`

`- right. reflexivity.`

`- contradiction.`

`- inversion H. destruct IHx1; destruct IHx2; auto. rewrite H2. left. rewrite sum_id. apply H3.`

`rewrite H2. rewrite H3. rewrite sum_id. right. reflexivity.`

`rewrite H2. rewrite H3. right. rewrite sum_comm. rewrite sum_id. reflexivity.`

`rewrite H2. rewrite H3. rewrite sum_x_x. left. reflexivity.`

`- inversion H. destruct IHx1; destruct IHx2; auto. rewrite H2. left. rewrite mul_T0_x. reflexivity.`

`rewrite H2. left. rewrite mul_T0_x. reflexivity.`

`rewrite H3. left. rewrite mul_comm. rewrite mul_T0_x. reflexivity.`

`rewrite H2. rewrite H3. right. rewrite mul_id. reflexivity.`

`Qed.`

This lemma, while intuitively obvious by definition, nonetheless provides a formal bridge between the world of ground terms and the world of variable sets.

Lemma `ground_term_has_empty_var_set` :

$\forall x, (\text{ground_term } x) \rightarrow (\text{term_vars } x) = [].$

Proof.

`intros. induction x.`

`- simpl. reflexivity.`

`- simpl. reflexivity.`

`- contradiction.`

`- firstorder. unfold term_vars. unfold term_vars in H2. rewrite H2. unfold term_vars in H1. rewrite H1. simpl. reflexivity.`

`- firstorder. unfold term_vars. unfold term_vars in H2. rewrite H2. unfold term_vars in H1. rewrite H1. simpl. reflexivity.`

`Qed.`

2.4.3 Examples

Here are some examples to show that our ground term definition is working appropriately.

```
Example ex_gt1 :  
  (ground_term (T0 + T1)).  
Proof.  
simpl. split.  
- reflexivity.  
- reflexivity.  
Qed.  
  
Example ex_gt2 :  
  (ground_term (VAR 0 × T1)) → False.  
Proof.  
simpl. intros. destruct H. apply H.  
Qed.
```

2.5 Substitutions

It is at this point in our Coq development that we begin to officially define the principal action around which the entirety of our efforts are centered: the act of substituting variables with other terms. While substitutions alone are not of great interest, their emergent properties as in the case of whether or not a given substitution unifies an equation are of substantial importance to our later research.

2.5.1 Definitions

Here we define a substitution to be a list of ordered pairs where each pair represents a variable being mapped to a term. For sake of clarity these ordered pairs shall be referred to as replacements from now on and as a result, substitutions should really be considered to be lists of replacements.

Definition replacement := (**prod** var term).

Definition subst := **list** replacement.

Implicit Type s : subst.

Our first function, find_replacement, is an auxilliary to apply_subst. This function will search through a substitution for a specific variable, and if found, returns the variable's associated term.

```
Fixpoint find_replacement (x : var) (s : subst) : term :=  
  match s with  
  | nil ⇒ VAR x  
  | r :: r' ⇒
```

```

    if beq_nat (fst r) x then (snd r)
  else
    (find_replacement x r')
end.

```

The `apply_subst` function will take a term and a substitution and will produce a new term reflecting the changes made to the original one.

```

Fixpoint apply_subst (t : term) (s : subst) : term :=
  match t with
  | T0 ⇒ T0
  | T1 ⇒ T1
  | VAR x ⇒ (find_replacement x s)
  | PRODUCT x y ⇒ PRODUCT (apply_subst x s) (apply_subst y s)
  | SUM x y ⇒ SUM (apply_subst x s) (apply_subst y s)
  end.

```

For reasons of completeness, it is useful to be able to generate identity substitutions; namely, substitutions that map the variables of a term's variable set to themselves.

```

Fixpoint build_id_subst (lvar : var_set) : subst :=
  match lvar with
  | nil ⇒ nil
  | v :: v' ⇒ (cons (v , (VAR v))
                    (build_id_subst v'))
  end.

```

Since we now have the ability to generate identity substitutions, we should now formalize a general proposition for testing whether or not a given substitution is an identity substitution of a given term.

```

Definition subst_equiv (s1 s2: subst) : Prop :=
  ∀ t, apply_subst t s1 == apply_subst t s2.

```

```

Definition subst_is_id_subst (t : term) (s : subst) : Prop :=
  (apply_subst t s) == t.

```

2.5.2 Lemmas

Having now outlined the functionality of a substitution, let us now begin to analyze some implications of its form and composition by proving some lemmas.

Given that we have a definition for identity substitutions, we should prove that identity substitutions do not modify a term.

Lemma `id_subst`:

```

  ∀ (t : term) (l : var_set),
  apply_subst t (build_id_subst l) == t.

```

Proof.

```

intros. induction t.
{
  simpl. reflexivity.
}
{
  simpl. reflexivity.
}
{
  simpl. induction l.
  {
    simpl. reflexivity.
  }
  {
    simpl. destruct (beq_nat a v) eqn: e.
    {
      apply beq_nat_true in e. rewrite e. reflexivity.
    }
    {
      apply IHL.
    }
  }
}
}
{
  simpl. rewrite IHt1. rewrite IHt2. reflexivity.
}
{
  simpl. rewrite IHt1. rewrite IHt2. reflexivity.
}
Qed.

Lemma apply_subst_compat :  $\forall (t \ t' : \text{term}),$ 
   $t == t' \rightarrow \forall (\text{sigma} : \text{subst}), (\text{apply\_subst } t \ \text{sigma}) == (\text{apply\_subst } t' \ \text{sigma}).$ 
Proof.
intros. induction t.
- induction t'.
+ simpl. reflexivity.
+ simpl. apply H.
+ simpl. rewrite H.
Admitted.

Add Parametric Morphism : apply_subst with
  signature eqv ==> eq ==> eqv as apply_subst_mor.
Proof.
  exact apply_subst_compat.

```

Qed.

An easy thing to prove right off the bat is that ground terms, i.e. terms with no variables, cannot be modified by applying substitutions to them. This will later prove to be very relevant when we begin to talk about unification.

Lemma ground_term_cannot_subst :

$\forall x, (\text{ground_term } x) \rightarrow (\forall s, \text{apply_subst } x \ s == x).$

Proof.

intros. induction s.

- apply ground_term_equiv_T0_T1 in H. destruct H.
+ rewrite H. simpl. reflexivity.
+ rewrite H. simpl. reflexivity.
- apply ground_term_equiv_T0_T1 in H. destruct H. rewrite H.
+ simpl. reflexivity.
+ rewrite H. simpl. reflexivity.

Qed.

A fundamental property of substitutions is their distributivity and associativity across the summation and multiplication of terms. Again the importance of these proofs will not become apparent until we talk about unification.

Lemma subst_distribution :

$\forall s \ x \ y, \text{apply_subst } x \ s + \text{apply_subst } y \ s == \text{apply_subst } (x + y) \ s.$

Proof.

intro. induction s. simpl. intros. reflexivity. intros. simpl. reflexivity.

Qed.

Lemma subst_associative :

$\forall s \ x \ y, \text{apply_subst } x \ s \times \text{apply_subst } y \ s == \text{apply_subst } (x \times y) \ s.$

Proof.

intro. induction s. intros. reflexivity. intros. simpl. reflexivity.

Qed.

Lemma subst_sum_distr_opp :

$\forall s \ x \ y, \text{apply_subst } (x + y) \ s == \text{apply_subst } x \ s + \text{apply_subst } y \ s.$

Proof.

intros.
apply refl_comm.
apply subst_distribution.

Qed.

Lemma subst_mul_distr_opp :

$\forall s \ x \ y, \text{apply_subst } (x \times y) \ s == \text{apply_subst } x \ s \times \text{apply_subst } y \ s.$

Proof.

intros.
apply refl_comm.
apply subst_associative.

Qed.

Lemma var_subst:

$\forall (v : \text{var}) (ts : \text{term}) ,$
 $(\text{apply_subst } (\text{VAR } v) (\text{cons } (v , ts) \text{ nil})) == ts.$

Proof.

intros. simpl. destruct (beq_nat v v) eqn: e. apply beq_nat_true in e.

reflexivity. apply beq_nat_false in e. firstorder.

Qed.

2.5.3 Examples

Here are some examples showcasing the nature of applying substitutions to terms.

Example subst_ex1 :

$(\text{apply_subst } (T0 + T1) []) == T0 + T1.$

Proof.

intros. reflexivity.

Qed.

Example subst_ex2 :

$(\text{apply_subst } (\text{VAR } 0 \times \text{VAR } 1) [(0, T0)]) == T0.$

Proof.

intros. simpl. apply mul_T0_x.

Qed.

2.6 Unification

Now that we have established the concept of term substitutions in Coq, it is time for us to formally define the concept of Boolean unification. Unification, in its most literal sense, refers to the act of applying a substitution to terms in order to make them equivalent to each other. In other words, to say that two terms are unifiable is to really say that there exists a substitution such that the two terms are equal. Interestingly enough, we can abstract this concept further to simply saying that a single term is unifiable if there exists a substitution such that the term will be equivalent to 0. By doing this abstraction, we can prove that equation solving and unification are essentially the same fundamental problem.

Below is the initial definition for unification, namely that two terms can be unified to be equivalent to one another. By starting here we will show each step towards abstracting unification to refer to a single term.

Definition unifies (a b : term) (s : subst) : Prop :=
 $(\text{apply_subst } a s) == (\text{apply_subst } b s).$

Here is a simple example demonstrating the concept of testing whether two terms are unified by a substitution.

Example ex_unif1 :
 unifies (VAR 0) (VAR 1) ((0, T1) :: (1, T1) :: nil).

Proof.

unfold unifies. simpl. reflexivity.

Qed.

Now we are going to show that moving both terms to one side of the equivalence relation through addition does not change the concept of unification.

Definition unifies_T0 (a b : term) (s : subst) : Prop :=
 (apply_subst a s) + (apply_subst b s) == T0.

Lemma unifies_T0_equiv :

$\forall x y s, \text{unifies } x y s \leftrightarrow \text{unifies_T0 } x y s.$

Proof.

intros. split.

```
{
  intros. unfold unifies_T0. unfold unifies in H. rewrite H.
  rewrite sum_x_x. reflexivity.
}
{
  intros. unfold unifies_T0 in H. unfold unifies.
  rewrite term_sum_symmetric with (x := apply_subst x s + apply_subst y s)
  (z := apply_subst y s) in H. rewrite sum_id in H.
  rewrite sum_comm in H.
  rewrite sum_comm with (y := apply_subst y s) in H.
  rewrite ← sum_assoc in H.
  rewrite sum_x_x in H.
  rewrite sum_id in H.
  apply H.
}
Qed.
```

Now we can define what it means for a substitution to be a unifier for a given term.

Definition unifier (t : term) (s : subst) : Prop :=
 (apply_subst t s) == T0.

Example unifier_ex1 :

(unifier (VAR 0) ((0, T0) :: nil)).

Proof.

unfold unifier. simpl. reflexivity.

Qed.

To ensure our efforts were not in vain, let us now prove that this last abstraction of the unification problem is still equivalent to the original.

Lemma unifier_distribution :

```

  ∀ x y s, (unifies_T0 x y s) ↔ (unifier (x + y) s).
Proof.
intros. split.
{
  intros. unfold unifies_T0 in H. unfold unifier.
  rewrite ← H. symmetry. apply subst_distribution.
}
{
  intros. unfold unifies_T0. unfold unifier in H.
  rewrite ← H. apply subst_distribution.
}
Qed.

```

Lastly let us define a term to be unifiable if there exists a substitution that unifies it.

```

Definition unifiable (t : term) : Prop :=
  ∃ s, unifier t s.
Example unifiable_ex1 :
  ∃ x, unifiable (x + T1).
Proof.
∃ (T1). unfold unifiable. unfold unifier.
∃ nil. simpl. rewrite sum_x_x. reflexivity.
Qed.

```

2.7 Most General Unifier

```

Definition substitution_composition (s s' delta : subst) (t : term) : Prop :=
  ∀ (x : var), apply_subst (apply_subst (VAR x) s) delta == apply_subst (VAR x) s'.
Definition more_general_substitution (s s' : subst) (t : term) : Prop :=
  ∃ delta, substitution_composition s s' delta t.
Definition most_general_unifier (t : term) (s : subst) : Prop :=
  (unifier t s) → (∀ (s' : subst), unifier t s' → more_general_substitution s s' t).
Definition reproductive_unifier (t : term) (sig : subst) : Prop :=
  unifier t sig →
  ∀ (tau : subst) (x : var),
  unifier t tau →
  (apply_subst (apply_subst (VAR x) sig) tau) == (apply_subst (VAR x) tau).
Lemma reproductive_is_mgu : ∀ (t : term) (u : subst),
  reproductive_unifier t u →
  most_general_unifier t u.
Proof.

```

```

intros. unfold most_general_unifier. unfold reproductive_unifier in H.
  unfold more_general_substitution . unfold substitution_composition.
  intros. specialize (H H0).  $\exists s'$ . intros. specialize (H s' x). specialize (H
H1). apply H.
Qed.

```

Lemma `most_general_unifier_compat` : $\forall (t \ t' : \text{term})$,
 $t == t' \rightarrow \forall (\text{sigma} : \text{subst}), (\text{most_general_unifier } t \ \text{sigma}) \leftrightarrow (\text{most_general_unifier } t'$
 $\text{sigma})$.

Proof.

Admitted.

2.8 Auxilliary Computational Operations and Simplifications

These functions below will come in handy later during the Lowenheim formula proof.

Fixpoint `identical` ($a \ b : \text{term}$) : `bool` :=

```

  match a , b with
  | T0, T0  $\Rightarrow$  true
  | T0, _  $\Rightarrow$  false
  | T1, T1  $\Rightarrow$  true
  | T1, _  $\Rightarrow$  false
  | VAR x , VAR y  $\Rightarrow$  if beq_nat x y then true else false
  | VAR x, _  $\Rightarrow$  false
  | PRODUCT x y, PRODUCT x1 y1  $\Rightarrow$  if ((identical x x1) && (identical y y1)) then
true
                                     else false
  | PRODUCT x y, _  $\Rightarrow$  false
  | SUM x y, SUM x1 y1  $\Rightarrow$  if ((identical x x1) && (identical y y1)) then true
                                     else false
  | SUM x y, _  $\Rightarrow$  false
end.

```

Definition `plus_one_step` ($a \ b : \text{term}$) : `term` :=

```

  match a, b with
  | T0, T0  $\Rightarrow$  T0
  | T0, T1  $\Rightarrow$  T1
  | T1, T0  $\Rightarrow$  T1
  | T1, T1  $\Rightarrow$  T0
  | _ , _  $\Rightarrow$  SUM a b
end.

```

Definition `mult_one_step` ($a \ b : \text{term}$) : `term` :=

```

match a, b with
| T0, T0 ⇒ T0
| T0, T1 ⇒ T0
| T1, T0 ⇒ T0
| T1, T1 ⇒ T1
| -, - ⇒ PRODUCT a b
end.

```

Fixpoint simplify (*t* : **term**) : **term** :=

```

match t with
| T0 ⇒ T0
| T1 ⇒ T1
| VAR x ⇒ VAR x
| PRODUCT x y ⇒ mult_one_step (simplify x) (simplify y)
| SUM x y ⇒ plus_one_step (simplify x) (simplify y)
end.

```

Lemma pos_left_sum_compat : $\forall (t \ t1 \ t2 : \mathbf{term}),$
 $t == t1 \rightarrow \text{plus_one_step } t1 \ t2 == \text{plus_one_step } t \ t2.$

5.1 Introduction

The second half of the project revolves around the successive variable elimination algorithm for solving unification problems. While we could implement this algorithm with the same data structures used for Lowenheim's, this algorithm lends itself well to a new representation of terms as polynomials.

A polynomial is a list of monomials being added together, where a monomial is a list of variables being multiplied together. Since one of the rules is that $x * x = x$, we can guarantee that there are no repeated variables in any given monomial. Similarly, because $x + x = 0$, we can guarantee that there are no repeated monomials in a polynomial.

Because of these properties, as well as the commutativity of addition and multiplication, we can represent both monomials and polynomials as unordered sets of variables and monomials, respectively. For simplicity when implementing and comparing these polynomials in Coq, we have opted to use the standard list structure, instead maintaining that the lists are maintained in our polynomial form after each stage.

In order to effectively implement polynomial lists in this way, a set of utilities are needed to allow us to easily perform operations on these lists. This file serves to implement and prove facts about these functions, as well as to expand upon the standard library when necessary.

5.2 Comparisons Between Lists

Checking if a list of natural numbers is sorted is easy enough. Comparing lists of lists of nats is slightly harder, and requires the use of a new function, called `lex`. `lex` simply takes in a comparison and applies the comparison across the list until it finds a point where the elements are not equal.

In all cases throughout this project, the comparator used will be the standard `nat compare` function.

For example, `[1;2;3]` is less than `[1;2;4]`, and `[1;2]` is greater than `[1]`.

```
Fixpoint lex {T : Type} (cmp : T → T → comparison) (l1 l2 : list T)
  : comparison :=
  match l1, l2 with
  | [], [] ⇒ Eq
  | [], _ ⇒ Lt
  | _, [] ⇒ Gt
  | h1 :: t1, h2 :: t2 ⇒
    match cmp h1 h2 with
    | Eq ⇒ lex cmp t1 t2
    | c ⇒ c
    end
  end.
```

There are some important but relatively straightforward properties of this function that are useful to prove. First, reflexivity:

Lemma `lex_nat_refl` : $\forall (l : \text{list nat}), \text{lex compare } l \ l = \text{Eq}$.

Proof.

```
intros.
induction l.
- simpl. reflexivity.
- simpl. rewrite compare_refl. apply IHL.
```

Qed.

Next, antisymmetry. This allows us to take a predicate or hypothesis about the comparison of two polynomials and reverse it.

For example, $a < b$ implies $b > a$.

Lemma `lex_nat_antisym` : $\forall (l1 \ l2 : \text{list nat}),$
 $\text{lex compare } l1 \ l2 = \text{CompOpp } (\text{lex compare } l2 \ l1).$

Proof.

```
intros l1.
induction l1.
- intros. simpl. destruct l2; reflexivity.
- intros. simpl. destruct l2.
  + simpl. reflexivity.
```

```

+ simpl. destruct (a ?= n) eqn:H;
  rewrite compare_antisym in H;
  rewrite CompOpp_iff in H; simpl in H;
  rewrite H; simpl.
  × apply IHl1.
  × reflexivity.
  × reflexivity.

```

Qed.

It is also useful to convert from the result of `lex compare` to a hypothesis about equality in Coq. Clearly, if `lex compare` returns `Eq`, the lists are exactly equal, and if it returns `Lt` or `Gt` they are not.

Lemma `lex_eq` : $\forall n m,$
`lex compare n m = Eq` $\leftrightarrow n = m$.

Proof.

```

intros n. induction n; induction m; intros.
- split; reflexivity.
- split; intros; inversion H.
- split; intros; inversion H.
- split; intros; simpl in H.
  + destruct (a ?= a0) eqn:Hcomp; try inversion H. f_equal.
    × apply compare_eq_iff in Hcomp; auto.
    × apply IHn. auto.
  + inversion H. simpl. rewrite compare_refl.
    rewrite ← H2. apply IHn. reflexivity.

```

Qed.

Lemma `lex_neq` : $\forall n m,$
`lex compare n m = Lt` \vee `lex compare n m = Gt` $\leftrightarrow n \neq m$.

Proof.

```

intros n. induction n; induction m.
- simpl. split; intro. inversion H; inversion H0. contradiction.
- simpl. split; intro. intro. inversion H0. auto.
- simpl. split; intro. intro. inversion H0. auto.
- clear IHm. split; intros.
  + destruct H; intro; apply lex_eq in H0; rewrite H in H0; inversion H0.
  + destruct (a ?= a0) eqn:Hcomp.
    × simpl. rewrite Hcomp. apply IHn. apply compare_eq_iff in Hcomp.
      rewrite Hcomp in H. intro. apply H. rewrite H0. reflexivity.
    × left. simpl. rewrite Hcomp. reflexivity.
    × right. simpl. rewrite Hcomp. reflexivity.

```

Qed.

Lemma `lex_neq'` : $\forall n m,$

(lex compare $n\ m = \text{Lt} \rightarrow n \neq m$) \wedge
 (lex compare $n\ m = \text{Gt} \rightarrow n \neq m$).

Proof.

```
intros n m. split.
- intros. apply lex_neq. auto.
- intros. apply lex_neq. auto.
```

Qed.

It is also useful to be able to flip the arguments of a call to lex **compare**, since these two comparisons impact each other directly.

If lex returns that $n = m$, then this also means that $m = n$. More interesting is that if $n < m$, then $m > n$.

Lemma lex_rev_eq : $\forall\ n\ m$,

lex compare $n\ m = \text{Eq} \leftrightarrow$ lex compare $m\ n = \text{Eq}$.

Proof.

```
intros n m. split; intro; rewrite lex_nat_antisym in H; unfold CompOpp in H.
- destruct (lex compare m n) eqn:H0; inversion H. reflexivity.
- destruct (lex compare n m) eqn:H0; inversion H. reflexivity.
```

Qed.

Lemma lex_rev_lt_gt : $\forall\ n\ m$,

lex compare $n\ m = \text{Lt} \leftrightarrow$ lex compare $m\ n = \text{Gt}$.

Proof.

```
intros n m. split; intro; rewrite lex_nat_antisym in H; unfold CompOpp in H.
- destruct (lex compare m n) eqn:H0; inversion H. reflexivity.
- destruct (lex compare n m) eqn:H0; inversion H. reflexivity.
```

Qed.

Lastly is a property over lists. The comparison of two lists stays the same if the same new element is added onto the front of each list. Similarly, if the item at the front of two lists is equal, removing it from both does not change the lists' comparison.

Lemma lex_nat_cons : $\forall\ (l1\ l2 : \text{list nat})\ n$,

lex compare $l1\ l2 =$ lex compare $(n :: l1)\ (n :: l2)$.

Proof.

```
intros. simpl. rewrite compare_refl. reflexivity.
```

Qed.

Hint Resolve lex_nat_refl lex_nat_antisym lex_nat_cons.

5.3 Extensions to the Standard Library

There were some facts about the standard library list functions that we found useful to prove, as they repeatedly came up in proofs of our more complex custom list functions.

Specifically, because we are comparing sorted lists, it is often easier to disregard the sortedness of the lists and instead compare them as Permutations of one another. As a result, many of the lemmas in the rest of this file revolve around proving that two lists are Permutations of one another.

5.3.1 Facts about **ln**

First, a very simple fact about **ln**. This mostly follows from the standard library lemma **Permutation_in**, but is more convenient for some of our proofs when formalized like this.

Lemma **Permutation_not_ln** : $\forall (A:\text{Type})\ a\ (l\ l':\text{list}\ A),$

Permutation $l\ l' \rightarrow$

$\neg \text{ln}\ a\ l \rightarrow$

$\neg \text{ln}\ a\ l'.$

Proof.

`intros A a l l' H H0. intro. apply H0. apply Permutation_sym in H.`

`apply (Permutation_in a) in H; auto.`

Qed.

Something else that seems simple but proves very useful to know is that if there are no elements **ln** a list, that list must be empty.

Lemma **nothing_in_empty** : $\forall \{A\}\ (l:\text{list}\ A),$

$(\forall a, \neg \text{ln}\ a\ l) \rightarrow$

$l = [].$

Proof.

`intros A l H. destruct l; auto. pose (H a). simpl in n. exfalso.`

`apply n. auto.`

Qed.

5.3.2 Facts about **incl**

Next are some useful lemmas about **incl**. First is that if one list is included in another, but one element of the second list is not in the first, then the first list is still included in the second with that element removed.

Lemma **incl_not_in** : $\forall A\ a\ (l\ m : \text{list}\ A),$

incl $l\ (a :: m) \rightarrow$

$\neg \text{ln}\ a\ l \rightarrow$

incl $l\ m.$

Proof.

`intros A a l m Hincl Hnin. unfold incl in *. intros a0 Hin.`

`simpl in Hincl. destruct (Hincl a0); auto. rewrite H in Hnin. contradiction.`

Qed.

We also found it useful to relate **Permutation** to **incl**; if two lists are permutations of each other, then they must be set equivalent, or contain all of the same elements.

Lemma Permutation_incl : $\forall \{A\} (l \ m : \text{list } A),$

Permutation $l \ m \rightarrow \text{incl } l \ m \wedge \text{incl } m \ l.$

Proof.

intros $A \ l \ m \ H.$ apply **Permutation_sym** in H as $H0.$ split.

+ unfold **incl.** intros $a.$ apply (**Permutation_in** - H).

+ unfold **incl.** intros $a.$ apply (**Permutation_in** - $H0$).

Qed.

Unfortunately, the definition above cannot be changed into an iff relation, as **incl** proves nothing about the counts in the lists. We can, however, prove that if some m includes all the elements of a list, then it also includes all the elements of all permutations of that list.

Lemma incl_Permutation : $\forall \{A:\text{Type}\} (l \ l' \ m:\text{list } A),$

Permutation $l \ l' \rightarrow$

incl $l \ m \rightarrow$

incl $l' \ m.$

Proof.

intros $A \ l \ l' \ m \ H \ H0.$ apply **Permutation_incl** in H as $[]$.

apply **incl_tran** with $(m:=l);$ auto.

Qed.

A really simple lemma is that if some l is included in the empty list, then that list must also be empty.

Lemma incl_nil : $\forall \{X:\text{Type}\} (l:\text{list } X),$

incl $l \ [] \leftrightarrow l = [].$

Proof.

intros $X \ l.$ unfold **incl.** split; intro $H.$

- destruct $l;$ [auto | destruct $(H \ x);$ intuition].

- intros $a \ Hin.$ destruct $l;$ [auto | rewrite H in $Hin;$ auto].

Qed.

The last fact about **incl** is simply a new way of formalizing the definition that is convenient for some proofs.

Lemma incl_cons_inv : $\forall (A:\text{Type}) (a:A) (l \ m : \text{list } A),$

incl $(a :: l) \ m \rightarrow \text{In } a \ m \wedge \text{incl } l \ m.$

Proof.

intros $A \ a \ l \ m \ H.$ split.

- unfold **incl** in $H.$ apply $H.$ intuition.

- unfold **incl** in $*$. intros $b \ Hin.$ apply $H.$ intuition.

Qed.

5.3.3 Facts about **count_occ**

Next is some facts about **count_occ**. Firstly, if two lists are permutations of each other, than every element in the first list has the same number of occurrences in the second list.

Lemma count_occ_Permutation : $\forall (A:\text{Type}) \text{Aeq_dec } a (l \ l':\text{list } A),$
Permutation $l \ l' \rightarrow$
count_occ $\text{Aeq_dec } l \ a = \text{count_occ } \text{Aeq_dec } l' \ a.$

Proof.

```
intros A Aeq_dec a l l' H. induction H.
- auto.
- simpl. destruct (Aeq_dec x a); auto.
- simpl. destruct (Aeq_dec y a); destruct (Aeq_dec x a); auto.
- rewrite ← IHPermutation2. rewrite IHPermutation1. auto.
```

Qed.

count_occ also distributes over app, instead becoming addition, which is useful especially when dealing with count occurrences of concatenated lists during induction.

Lemma count_occ_app : $\forall (A:\text{Type}) \ a (l \ m:\text{list } A) \ \text{Aeq_dec},$
count_occ $\text{Aeq_dec } (l++m) \ a = \text{add } (\text{count_occ } \text{Aeq_dec } l \ a) \ (\text{count_occ } \text{Aeq_dec } m \ a).$

Proof.

```
intros A a l m Aeq_dec. induction l.
- simpl. auto.
- simpl. destruct (Aeq_dec a0 a); simpl; auto.
```

Qed.

It is also convenient to reason about the relation between **count_occ** and **remove**. If the element being removed is the same as the one being counted, then the count is obviously 0; if the elements are different, then the count is the same with or without the remove.

Lemma count_occ_remove : $\forall \{A\} \ \text{Aeq_dec } (a:A) \ p,$
count_occ $\text{Aeq_dec } (\text{remove } \text{Aeq_dec } a \ p) \ a = 0.$

Proof.

```
intros A Aeq_dec a p. induction p.
- simpl. auto.
- simpl. destruct (Aeq_dec a a0) eqn:Haa0.
  + apply IHp.
  + simpl. destruct (Aeq_dec a0 a); try (symmetry in e; contradiction).
    apply IHp.
```

Qed.

Lemma count_occ_neq_remove : $\forall \{A\} \ \text{Aeq_dec } (a:A) \ b \ p,$
 $a \neq b \rightarrow$
count_occ $\text{Aeq_dec } (\text{remove } \text{Aeq_dec } a \ p) \ b =$
count_occ $\text{Aeq_dec } p \ b.$

Proof.

```
intros A Aeq_dec a b p H. induction p; simpl; auto. destruct (Aeq_dec a a0).
- destruct (Aeq_dec a0 b).
  + rewrite ← e0 in H. rewrite e in H. contradiction.
  + apply IHp.
```

```
- simpl. destruct (Aeq_dec a0 b); auto.
Qed.
```

5.3.4 Facts about **concat**

Similarly to the lemma **Permutation_map**, **Permutation_concat** shows that if two lists are permutations of each other then the concatenation of each list are also permutations.

Lemma **Permutation_concat** : $\forall \{A\} (l\ m:\text{list } (A)),$

Permutation $l\ m \rightarrow$
Permutation (**concat** l) (**concat** m).

Proof.

```
intros A l m H. induction H.
- auto.
- simpl. apply Permutation_app_head. auto.
- simpl. apply Permutation_trans with (l':=(concat l ++ y ++ x)).
  + rewrite app_assoc. apply Permutation_app_comm.
  + apply Permutation_trans with (l':=(concat l ++ x ++ y)).
    × apply Permutation_app_head. apply Permutation_app_comm.
    × rewrite (app_assoc x y). apply Permutation_app_comm.
- apply Permutation_trans with (l':=(concat l')); auto.
```

Qed.

Before the creation of this lemma, it was relatively hard to reason about whether elements are in the concatenation of a list of lists. This lemma states that if there is a list in the list of lists that contains the desired element, then that element will be in the concatenated version.

Lemma **In_concat_exists** : $\forall (A:\text{Type})\ ll\ (a:A),$

$(\exists l, \text{In } l\ ll \wedge \text{In } a\ l) \leftrightarrow \text{In } a\ (\text{concat } ll).$

Proof.

```
intros A ll a. split; intros H.
- destruct H as [l[]]. apply In_split in H. destruct H as [l1[l2 H]].
  rewrite H. apply Permutation_in with (l:=(concat (l :: l1 ++ l2))).
  + apply Permutation_concat. apply Permutation_middle.
  + simpl. apply in_app_iff. auto.
- induction ll.
  + inversion H.
  + simpl in H. apply in_app_iff in H. destruct H.
    ×  $\exists a0$ . split; intuition.
    × destruct IHll; auto.  $\exists x$ . intuition.
```

Qed.

This particular lemma is useful if the function being mapped returns a list of its input type. If the resulting lists are concatenated after, then the result is the same as mapping the function without converting the output to lists.

Lemma concat_map : $\forall \{A B:\text{Type}\} (f:A \rightarrow B) (l:\text{list } A),$
 $\text{concat } (\text{map } (\text{fun } a \Rightarrow [f \ a]) \ l) = \text{map } f \ l.$

Proof.

```
intros A B f l. induction l.
- auto.
- simpl. f_equal. apply IHl.
```

Qed.

Lastly, if you **map** a function that converts every element of a list to **nil**, and then **concat** the list of **nil**s, you end with **nil**.

Lemma concat_map_nil : $\forall \{A\} (p:\text{list } A),$
 $\text{concat } (\text{map } (\text{fun } x \Rightarrow []) \ p) = (@\text{nil } A).$

Proof.

```
induction p; auto.
```

Qed.

5.3.5 Facts about **Forall** and **existsb**

This is similar to the inverse of **Forall**; any element in the list must hold the specified relation if **Forall** *Rel* is true of the list.

Lemma Forall_In : $\forall (A:\text{Type}) (l:\text{list } A) \ a \ \text{Rel},$
 $\text{In } a \ l \rightarrow \text{Forall } \text{Rel } l \rightarrow \text{Rel } a.$

Proof.

```
intros A l a Rel Hin Hfor. apply (Forall_forall Rel l); auto.
```

Qed.

In Coq, **existsb** is effectively the “or” to **Forall**’s “and” when reasoning about lists. If there does not exist a single element in the list where *f* is true, then (*f a*) must be false for all elements of the list.

Lemma existsb_false_forall : $\forall \{A\} \ f \ (l:\text{list } A),$
 $\text{existsb } f \ l = \text{false} \rightarrow$
 $(\forall a, \text{In } a \ l \rightarrow (f \ a) = \text{false}).$

Proof.

```
intros A f l H a Hin. destruct (f a) eqn:Hfa.
- exfalso. rewrite ← Bool.negb_true_iff in H. apply (Bool.eq_true_false_abs _ H).
  rewrite Bool.negb_false_iff. apply existsb_exists.  $\exists$  a. split; auto.
- auto.
```

Qed.

Similarly to Forall_In, this lemma is just another way of formalizing the definition of Forall that proves useful when dealing with **StronglySorted** lists.

Lemma Forall_cons_iff : $\forall (A:\text{Type}) \ \text{Rel } a \ (l:\text{list } A),$
 $\text{Forall } \text{Rel } (a :: l) \leftrightarrow \text{Forall } \text{Rel } l \wedge \text{Rel } a.$

Proof.

```

intros A Rel a l. split.
- intro H. split.
  + rewrite Forall_forall in H. apply Forall_forall. intros x Hin.
    apply H. intuition.
  + apply Forall_inv in H. auto.
- intros []. apply Forall_cons; auto.
Qed.

```

If a relation holds for all elements of a list l , then the relation still holds if some elements are removed from the list.

Lemma Forall_remove : $\forall (A:\text{Type}) \text{Aeq_dec } Rel \ a \ (l:\text{list } A),$
 $\text{Forall } Rel \ l \rightarrow \text{Forall } Rel \ (\text{remove } \text{Aeq_dec } a \ l).$

Proof.

```

intros A Aeq_dec Rel a l H. induction l.
- simpl. auto.
- simpl. apply Forall_cons_iff in H. destruct (Aeq_dec a a0).
  + apply IHL. apply H.
  + apply Forall_cons_iff. split.
    × apply IHL. apply H.
    × apply H.

```

Qed.

This next lemma is particularly useful for relating **StronglySorted** lists to **Sorted** lists; if some comparator holds for all elements of p , then this can be converted to the **HdRel** proposition used by **Sorted**.

Lemma Forall_HdRel : $\forall \{X:\text{Type}\} \ c \ a \ (p:\text{list } X),$
 $\text{Forall } (c \ a) \ p \rightarrow \text{HdRel } c \ a \ p.$

Proof.

```

intros X c a p H. destruct p.
- apply HdRel_nil.
- apply HdRel_cons. apply Forall_inv in H. auto.

```

Qed.

Lastly, if some property $(c \ a)$ is true for all elements in a list p , and the elements of a second list g are all included in p , then the property is also true for the elements in g .

Lemma Forall_incl : $\forall \{X:\text{Type}\} \ (c:X \rightarrow X \rightarrow \text{Prop}) \ a \ (p \ g:\text{list } X),$
 $\text{Forall } (c \ a) \ p \rightarrow \text{incl } g \ p \rightarrow \text{Forall } (c \ a) \ g.$

Proof.

```

intros X c a p g H H0. induction g.
- apply Forall_nil.
- rewrite Forall_forall in H. apply Forall_forall. intros x Hin.
  apply H. unfold incl in H0. apply H0. intuition.

```

Qed.

5.3.6 Facts about **remove**

There are surprisingly few lemmas about **remove** in the standard library, so in addition to those proven in other places, we opted to add quite a few simple facts about **remove**. First is that if an element is in a list after something has been removed, then clearly it was in the list before as well.

Lemma `In_remove` : $\forall \{A:\text{Type}\} \text{Aeq_dec } a \ b \ (l:\text{list } A),$
 $\text{In } a \ (\text{remove } \text{Aeq_dec } b \ l) \rightarrow \text{In } a \ l.$

Proof.

```
intros A Aeq_dec a b l H. induction l as [|c l IHL].
- contradiction.
- destruct (Aeq_dec b c) eqn:Heq; simpl in H; rewrite Heq in H.
  + right. auto.
  + destruct H; [rewrite H; intuition | right; auto].
```

Qed.

Similarly to `Forall_remove`, if a list was **StronglySorted** before something was removed then it is also **StronglySorted** after.

Lemma `StronglySorted_remove` : $\forall \{A:\text{Type}\} \text{Aeq_dec } \text{Rel } a \ (l:\text{list } A),$
 $\text{StronglySorted } \text{Rel } l \rightarrow \text{StronglySorted } \text{Rel } (\text{remove } \text{Aeq_dec } a \ l).$

Proof.

```
intros A Aeq_dec Rel a l H. induction l.
- simpl. auto.
- simpl. apply StronglySorted_inv in H. destruct (Aeq_dec a a0).
  + apply IHL. apply H.
  + apply SSorted_cons.
    × apply IHL. apply H.
    × apply Forall_remove. apply H.
```

Qed.

If the item being removed from a list isn't in the list, then the list is equal with or without the remove.

Lemma `not_In_remove` : $\forall (A:\text{Type}) \text{Aeq_dec } a \ (l : \text{list } A),$
 $\neg \text{In } a \ l \rightarrow (\text{remove } \text{Aeq_dec } a \ l) = l.$

Proof.

```
intros A Aeq_dec a l H. induction l.
- simpl. reflexivity.
- simpl. destruct (Aeq_dec a a0).
  + simpl. rewrite e in H. exfalso. apply H. intuition.
  + rewrite IHL. reflexivity. intro Hin. apply H. intuition.
```

Qed.

remove also distributes over `append`.

Lemma `remove_distr_app` : $\forall (A:\text{Type}) \text{Aeq_dec } x \ (l \ l':\text{list } A),$

`remove Aeq_dec x (l ++ l') = remove Aeq_dec x l ++ remove Aeq_dec x l'.`

Proof.

```
intros A Aeq_dec x l l'. induction l; intros.
- simpl. auto.
- simpl. destruct (Aeq_dec x a).
  + apply IHL.
  + simpl. f_equal. apply IHL.
```

Qed.

More interestingly, if two lists were permutations before, they are also permutations after the same element has been removed from both lists.

Lemma `remove_Permutation` : $\forall (A:\text{Type}) \text{Aeq_dec } a (l \text{ l':list } A),$
`Permutation l l' →`
`Permutation (remove Aeq_dec a l) (remove Aeq_dec a l').`

Proof.

```
intros A Aeq_dec a l l' H. induction H.
- auto.
- simpl. destruct (Aeq_dec a x); auto.
- simpl. destruct (Aeq_dec a y); destruct (Aeq_dec a x); auto.
  apply perm_swap.
- apply Permutation_trans with (l':=(remove Aeq_dec a l')); auto.
```

Qed.

`remove` is also commutative with itself.

Lemma `remove_remove` : $\forall \{A:\text{Type}\} \text{Aeq_dec } (a \text{ b:A}) p,$
`remove Aeq_dec a (remove Aeq_dec b p) =`
`remove Aeq_dec b (remove Aeq_dec a p).`

Proof.

```
intros A Aeq_dec a b p. induction p as [|c]; simpl; auto.
destruct (Aeq_dec a b); destruct (Aeq_dec b c); destruct (Aeq_dec a c).
- auto.
- rewrite ← e0 in n. rewrite e in n. contradiction.
- rewrite ← e in n. rewrite e0 in n. contradiction.
- simpl. destruct (Aeq_dec a c); try contradiction.
  destruct (Aeq_dec b c); try contradiction. rewrite IHp. auto.
- rewrite e in n. rewrite e0 in n. contradiction.
- simpl. destruct (Aeq_dec b c); try contradiction. auto.
- simpl. destruct (Aeq_dec a c); try contradiction. auto.
- simpl. destruct (Aeq_dec a c); try contradiction.
  destruct (Aeq_dec b c); try contradiction. rewrite IHp. auto.
```

Qed.

Lastly, if an element is being removed from a particular list twice, the inner `remove` is redundant and can be removed.

Lemma remove_pointless : $\forall \{A \text{ Aeq_dec}\} (a:A) p q,$
 $\text{remove } Aeq_dec \ a \ (\text{remove } Aeq_dec \ a \ p \ ++ \ q) =$
 $\text{remove } Aeq_dec \ a \ (p \ ++ \ q).$

Proof.

```
intros A Aeq_dec a p q. induction p; auto. simpl. destruct (Aeq_dec a a0) eqn:Heq.
- apply IHp.
- simpl. rewrite Heq. f_equal. apply IHp.
```

Qed.

5.3.7 Facts about **nodup** and **NoDup**

Next up - the NoDup proposition and the closely related nodup function. The first lemma states that if there are no duplicates in a list, then two items in that list must not be equal.

Lemma NoDup_neq : $\forall \{X:\text{Type}\} (m : \text{list } X) a b,$
 $\text{NoDup } (a :: b :: m) \rightarrow$
 $a \neq b.$

Proof.

```
intros X m a b Hdup. apply NoDup_cons_iff in Hdup as [].
apply NoDup_cons_iff in H0 as []. intro. apply H. simpl. auto.
```

Qed.

In a similar vein as many of the other **remove** lemmas, if there were no duplicates in a list before the **remove** then there are still none after.

Lemma NoDup_remove : $\forall (A:\text{Type}) \text{ Aeq_dec } a (l:\text{list } A),$
 $\text{NoDup } l \rightarrow \text{NoDup } (\text{remove } Aeq_dec \ a \ l).$

Proof.

```
intros A Aeq_dec a l H. induction l.
- simpl. auto.
- simpl. destruct (Aeq_dec a a0).
  + apply IHL. apply NoDup_cons_iff in H. intuition.
  + apply NoDup_cons.
    × apply NoDup_cons_iff in H as []. intro. apply H.
      apply (ln_remove Aeq_dec a0 a l H1).
    × apply IHL. apply NoDup_cons_iff in H; intuition.
```

Qed.

Another lemma similar to NoDup_neq is NoDup_forall_neq; if every element in a list is not equal to a certain a , and the list has no duplicates as is, then it is safe to add a to the list without creating duplicates.

Lemma NoDup_forall_neq : $\forall (A:\text{Type}) a (l:\text{list } A),$
 $\text{Forall } (\text{fun } b \Rightarrow a \neq b) \ l \rightarrow$
 $\text{NoDup } l \rightarrow$
 $\text{NoDup } (a :: l).$

Proof.

```

intros A a l Hf Hn. apply NoDup_cons.
- intro. induction l.
  + inversion H.
  + apply Forall_cons_iff in Hf as []. apply IHL.
    × apply H0.
    × apply NoDup_cons_iff in Hn. apply Hn.
    × simpl in H. destruct H; auto. rewrite H in H1. contradiction.
- auto.

```

Qed.

This lemma is really just a reformalization of `NoDup_remove_2`, which allows us to easily prove that some x is not in the preceding elements $l1$ or the following elements $l2$ when the whole list l has no duplicates.

Lemma NoDup_in_split : $\forall \{A:\text{Type}\} (x:A) l l1 l2,$
 $l = l1 ++ x :: l2 \rightarrow$
 $\text{NoDup } l \rightarrow$
 $\neg \text{In } x l1 \wedge \neg \text{In } x l2.$

Proof.

```

intros A x l l1 l2 H H0. rewrite H in H0.
apply NoDup_remove_2 in H0. split; intro; intuition.

```

Qed.

Now some facts about the function `nodup`; if the `NoDup` predicate is already true about a certain list, then calling `nodup` on it changes nothing.

Lemma no_nodup_NoDup : $\forall (A:\text{Type}) \text{Aeq_dec } (l:\text{list } A),$
 $\text{NoDup } l \rightarrow$
 $\text{nodup } \text{Aeq_dec } l = l.$

Proof.

```

intros A Aeq_dec l H. induction l.
- auto.
- simpl. apply NoDup_cons_iff in H as []. destruct (in_dec Aeq_dec a l).
  contradiction. f_equal. auto.

```

Qed.

If a list is sorted (with a transitive relation) before calling `nodup` on it, the list is also sorted after.

Lemma Sorted_nodup : $\forall (A:\text{Type}) \text{Aeq_dec } \text{Rel } (l:\text{list } A),$
 $\text{Relations_1.Transitive } \text{Rel} \rightarrow$
 $\text{Sorted } \text{Rel } l \rightarrow$
 $\text{Sorted } \text{Rel } (\text{nodup } \text{Aeq_dec } l).$

Proof.

```

intros A Aeq_dec Rel l Ht H. apply Sorted_StronglySorted in H; auto.
apply StronglySorted_Sorted. induction l.

```

```

- auto.
- simpl. apply StronglySorted_inv in H as []. destruct (in_dec Aeq_dec a l).
  + apply IHL. apply H.
  + apply SSorted_cons.
    × apply IHL. apply H.
    × rewrite Forall_forall in H0. apply Forall_forall. intros x Hin.
      apply H0. apply nodup_In in Hin. auto.

```

Qed.

And lastly, similarly to our other Permutation lemmas this far, if two lists were permutations of each other before **nodup** they are also permutations after.

This lemma was slightly more complex than previous Permutation lemmas, but the proof is still very similar. It is solved by induction on the Permutation hypothesis. The first and last cases are trivial, and the second case (where we must prove $\text{Permutation } (x::l) (x::l')$) becomes simple with the use of Permutation_in .

The last case (where we must show $\text{Permutation } (x::y::l) (y::x::l)$) was slightly complicated by the fact that destructing **in_dec** gives us a hypothesis like $\text{In } x (y::l)$, which seems useless in reasoning about the other list at first. However, by also destructing whether or not x and y are equal, we can easily prove this case as well

Lemma $\text{Permutation_nodup} : \forall A \text{ Aeq_dec } (l \text{ m} : \text{list } A),$

Permutation $l \text{ m} \rightarrow \text{Permutation } (\text{nodup } \text{Aeq_dec } l) (\text{nodup } \text{Aeq_dec } m).$

Proof.

```

intros. induction H.
- auto.
- simpl. destruct (in_dec Aeq_dec x l).
  + apply Permutation_in with (l' := l') in i; auto. destruct in_dec; try contradiction.
    auto.
  + assert (¬ In x l'). intro. apply n. apply Permutation_in with (l' := l) in H0; auto.
    apply Permutation_sym; auto. destruct in_dec; try contradiction.
    apply perm_skip. auto.
- destruct (in_dec Aeq_dec y (x :: l)). destruct i.
  + rewrite H. simpl. destruct (Aeq_dec y y); try contradiction. destruct in_dec.
    auto. apply perm_skip. auto.
  + simpl. destruct (Aeq_dec x y). destruct in_dec; destruct (Aeq_dec y x);
    try (symmetry in e; contradiction). rewrite e in i. destruct in_dec; try contradiction.
    auto. assert (¬ In y l). intro; apply n; rewrite e; auto.
    destruct in_dec; try contradiction. destruct in_dec; try contradiction.
    destruct in_dec; destruct (Aeq_dec y x); try (symmetry in e; contradiction).
    auto. apply perm_skip. auto.
  + simpl. destruct (Aeq_dec x y). destruct in_dec. destruct (Aeq_dec y x);
    try (symmetry in e; contradiction). rewrite e0. destruct in_dec; try contradiction.
    auto. destruct (Aeq_dec y x); try (symmetry in e; contradiction).
    assert (¬ In y l). intro; apply n0; rewrite e; auto. destruct in_dec; try

```

5.3.8 Facts about **partition**

The final function in the standard library we found it useful to prove facts about is **partition**. First, we show the relation between **partition** and **filter**: filtering a list gives you a result that is equal to the first list **partition** would return. This lemma is proven one way, and then reformalized to be more useful in later proofs.

Lemma partition_filter_fst $\{X\}$ p l :
fst (**partition** p l) = **@filter** X p l .

Proof.

```

    induction l; simpl.
  - trivial.
  - rewrite ← IHL.
    destruct (partition  $p$   $l$ ); simpl.
    destruct ( $p$   $a$ ); now simpl.

```

Qed.

Lemma partition_filter_fst' : $\forall \{X\}$ p (l t f : **list** X),
partition p l = (t , f) \rightarrow
 t = **@filter** X p l .

Proof.

```

    intros  $X$   $p$   $l$   $t$   $f$   $H$ .
    rewrite ← partition_filter_fst.
    now rewrite  $H$ .

```

Qed.

We would like to be able to state a similar fact about the second list returned by **partition**, but clearly these are all the elements “thrown out” by **filter**. Instead, we first create a simple definition for negating a function, and prove two quick facts about the relation between some p and **neg** p .

Definition **neg** $\{X:\text{Type}\}$:= fun ($f:X \rightarrow \text{bool}$) \Rightarrow fun ($a:X$) \Rightarrow (**negb** (f a)).

Lemma neg_true_false : $\forall \{X\}$ ($p:X \rightarrow \text{bool}$) ($a:X$),
 $(p$ a) = **true** \leftrightarrow **neg** p a = **false**.

Proof.

```

    intros  $X$   $p$   $a$ . unfold neg. split; intro.
  - rewrite  $H$ . auto.
  - destruct ( $p$   $a$ ); intuition.

```

Qed.

Lemma neg_false_true : $\forall \{X\} (p:X \rightarrow \text{bool}) (a:X),$
 $(p\ a) = \text{false} \leftrightarrow \text{neg } p\ a = \text{true}.$

Proof.

```
intros X p a. unfold neg. split; intro.  
- rewrite H. auto.  
- destruct (p a); intuition.
```

Qed.

With the addition of this `neg` proposition, we can now prove two lemmas relating the second `partition` list and `filter` in the same way we proved the lemmas about the first `partition` list.

Lemma partition_filter_snd $\{X\} p\ l :$
 $\text{snd } (\text{partition } p\ l) = @\text{filter } X\ (\text{neg } p)\ l.$

Proof.

```
induction l; simpl.  
- reflexivity.  
- rewrite  $\leftarrow$  IHL.  
  destruct (partition p l); simpl.  
  destruct (p a) eqn:Hp.  
  + simpl. apply neg_true_false in Hp. rewrite Hp; auto.  
  + simpl. apply neg_false_true in Hp. rewrite Hp; auto.
```

Qed.

Lemma partition_filter_snd' : $\forall \{X\} p\ (l\ t\ f : \text{list } X),$
 $\text{partition } p\ l = (t, f) \rightarrow$
 $f = @\text{filter } X\ (\text{neg } p)\ l.$

Proof.

```
intros X p l t f H.  
rewrite  $\leftarrow$  partition_filter_snd.  
now rewrite H.
```

Qed.

These lemmas about `partition` and `filter` are now put to use in two important lemmas about `partition`. If some list l is partitioned into two lists (t, f) , then every element in t must return true for the filtering predicate and every element in f must return false.

Lemma partfst_true : $\forall X\ p\ (l\ t\ f : \text{list } X),$
 $\text{partition } p\ l = (t, f) \rightarrow$
 $(\forall a, \text{In } a\ t \rightarrow p\ a = \text{true}).$

Proof.

```
intros X p l t f Hpart a Hin.  
assert (Hf:  $t = \text{filter } p\ l$ ).  
- now apply partition_filter_fst' with f.  
- assert (Hass := filter_In p a l).
```

```

    apply Hass.
    now rewrite ← Hf.

```

Qed.

Lemma part_snd_false : $\forall X p (x t f : \text{list } X),$
 $\text{partition } p x = (t, f) \rightarrow$
 $(\forall a, \text{In } a f \rightarrow p a = \text{false}).$

Proof.

```

    intros X p l t f Hpart a Hin.
    assert (Hf: f = filter (neg p) l).
    - now apply partition_filter_snd' with t.
    - assert (Hass := filter_In (neg p) a l).
      rewrite ← neg_false_true in Hass.
      apply Hass.
      now rewrite ← Hf.

```

Qed.

Next is a rather obvious but useful lemma, which states that if a list p was split into (l, r) then appending these lists back together results in a list that is a permutation of the original.

Lemma partition_Permutation : $\forall \{A:\text{Type}\} f (p l r : \text{list } A),$
 $\text{partition } f p = (l, r) \rightarrow$
 $\text{Permutation } p (l ++ r).$

Proof.

```

    intros A f p. induction p; intros.
    - simpl in H. inversion H. auto.
    - simpl in H. destruct (partition f p). destruct (f a); inversion H.
      + simpl. apply perm_skip. apply IHp. f_equal. auto.
      + apply Permutation_trans with (l':=(a :: l1 ++ l)). apply perm_skip.
        apply Permutation_trans with (l':=(l ++ l1)). apply IHp. f_equal.
        auto. apply Permutation_app_comm. apply Permutation_app_comm with (l:=(a :: l1)).

```

Qed.

The last and hardest fact about `partition` states that if the list being partitioned was already sorted, then the resulting two lists will also be sorted. This seems simple, as `partition` iterates through the elements in order and maintains the order in its children, but was surprisingly difficult to prove.

After performing induction, the next step was to destruct $(f a)$, to see which of the two lists the induction element would end up in. In both cases, the list that *doesn't* receive the new element is already clearly sorted by the induction hypothesis, but proving the other one is sorted is slightly harder.

By using `Forall_HdRel` (defined earlier), we reduced the problem in both cases to only having to show that the new element holds the relation c on all elements of the list it was consed onto. After some manipulation and the use of `partition_Permutation` and `Forall_incl`,

this follows from the fact that we know the new element holds the relation on all elements of the original list p , and therefore also holds it on the elements of the partitioned list.

Lemma `part_Sorted` : $\forall \{X:\text{Type}\} (c:X \rightarrow X \rightarrow \text{Prop}) f p,$

`Relations_1.Transitive` $c \rightarrow$

`Sorted` $c p \rightarrow$

$\forall l r, \text{partition } f p = (l, r) \rightarrow$

`Sorted` $c l \wedge \text{Sorted } c r.$

Proof.

Qed.

5.4 New Functions over Lists

In order to easily perform the operations we need on lists, we defined three major list functions of our own, each with their own proofs. These generalized list functions all help to make it much easier to deal with our polynomial and monomial lists later in the development.

5.4.1 Distributing two Lists: `distribute`

The first and most basic of the three is `distribute`. Similarly to the “FOIL” technique learned in middle school for multiplying two polynomials, this function serves to create every combination of one element from each list. It is done concisely with the use of higher order functions below.

Definition `distribute` $\{A\} (l\ m : \text{list } (\text{list } A)) : \text{list } (\text{list } A) :=$
`concat (map (fun a:(list A) => (map (app a) l)) m).`

The `distribute` function will play a larger role later, mostly as a part of our polynomial multiplication function. For now, however, there are only two very simple lemmas to be proven, both stating that distributing `nil` over a list results in `nil`.

Lemma `distribute_nil` : $\forall \{A:\text{Type}\} (p:\text{list } (\text{list } A)),$
`distribute [] p = [].`

Proof.

```
intros A p. induction p.
- auto.
- unfold distribute in *. simpl in *. auto.
```

Qed.

Lemma `distribute_nil_r` : $\forall \{A:\text{Type}\} (p:\text{list } (\text{list } A)),$
`distribute p [] = [].`

Proof.

```
intros A p. induction p.
- auto.
- unfold distribute in *. simpl in *. auto.
```

Qed.

5.4.2 Cancelling out Repeated Elements: `nodup_cancel`

The next list function, and possibly the most prolific function in our entire development, is `nodup_cancel`. Similarly to the standard library `nodup` function, `nodup_cancel` takes a list that may or may not have duplicates in it and returns a list without duplicates.

The difference between ours and the standard function is that rather than just removing all duplicates and leaving one of each element, the elements in a `nodup_cancel` list cancel out in pairs. For example, the list `[1;1;1]` would become `[1]`, whereas `[1;1;1;1]` would become `[]`.

This is implemented with the `count_occ` function and `remove`, and is largely the reason for needing so many lemmas about those two functions. If there is an *even* number of occurrences

of an element a in the original list ($a::l$), which implies there is an *odd* number of occurrences of this element in l , then all instances are removed. On the other hand, if there is an *odd* number of occurrences in the original list, one occurrence is kept, and the rest are removed.

By calling `nodup_cancel` recursively on xs *before* calling `remove`, Coq is easily able to determine that xs is the decreasing argument, removing the need for a more complicated definition with “fuel”.

```
Fixpoint nodup_cancel {A} Aeq_dec (l : list A) : list A :=
  match l with
  | [] => []
  | x::xs =>
    let count := (count_occ Aeq_dec xs x) in
    let xs' := (remove Aeq_dec x (nodup_cancel Aeq_dec xs)) in
    if (even count) then x::xs' else xs'
  end.
```

Now onto lemmas. To begin with, there are a few facts true of `nodup` that are also true of `nodup_cancel`, which are useful in many proofs. `nodup_cancel_in` is the same as the standard library’s `nodup_in`, with one important difference: this implication is *not* bidirectional. Because even parity elements are removed completely, not all elements in l are guaranteed to be in `nodup_cancel l`.

`NoDup_nodup_cancel` is much simpler, and effectively exactly the same as `NoDup_nodup`.

In these proofs, and most others from this point on, the shape will be very similar to the proof of the corresponding `nodup` proof. The main difference is that, instead of destructing `in_dec` like one would for `nodup`, we destruct the evenness of `count_occ`, as that is what drives the main if statement of the function.

```
Lemma nodup_cancel_in : ∀ (A:Type) Aeq_dec a (l:list A),
  In a (nodup_cancel Aeq_dec l) → In a l.
```

Proof.

```
  intros A Aeq_dec a l H. induction l as [|b l IHL].
  - contradiction.
  - simpl in H. destruct (Aeq_dec a b).
    + rewrite e. intuition.
    + right. apply IHL. destruct (even (count_occ Aeq_dec l b)).
      × simpl in H. destruct H. rewrite H in n. contradiction.
      apply In_remove in H. auto.
      × apply In_remove in H. auto.
```

Qed.

```
Lemma NoDup_nodup_cancel : ∀ (A:Type) Aeq_dec (l:list A),
  NoDup (nodup_cancel Aeq_dec l).
```

Proof.

```
  induction l as [|a l' Hrec]; simpl.
  - constructor.
```

```

- destruct (even (count_occ Aeq_dec l' a)); simpl.
+ apply NoDup_cons; [apply remove_in | apply NoDup_remove; auto].
+ apply NoDup_remove; auto.

```

Qed.

Although not standard library lemmas, the `no_nodup_NoDup` and `Sorted_nodup` facts we proved earlier in this file are also both true of `nodup_cancel`, and proven in almost the same way.

Lemma `no_nodup_cancel_NoDup` : $\forall (A:\text{Type}) \text{Aeq_dec } (l:\text{list } A),$
`NoDup` $l \rightarrow$
`nodup_cancel` $\text{Aeq_dec } l = l$.

Proof.

```

intros A Aeq_dec l H. induction l.
- auto.
- simpl. apply NoDup_cons_iff in H as []. assert (count_occ Aeq_dec l a = 0).
+ apply count_occ_not_in. auto.
+ rewrite H1. simpl. f_equal. rewrite not_in_remove. auto. intro.
  apply nodup_cancel_in in H2. apply H. auto.

```

Qed.

Lemma `Sorted_nodup_cancel` : $\forall (A:\text{Type}) \text{Aeq_dec } \text{Rel } (l:\text{list } A),$
`Relations_1.Transitive` $\text{Rel} \rightarrow$
`Sorted` $\text{Rel } l \rightarrow$
`Sorted` $\text{Rel } (\text{nodup_cancel } \text{Aeq_dec } l)$.

Proof.

```

intros A Aeq_dec Rel l Ht H. apply Sorted_StronglySorted in H; auto.
apply StronglySorted_Sorted. induction l.
- auto.
- simpl. apply StronglySorted_inv in H as []. destruct (even (count_occ Aeq_dec l a)).
+ apply SSorted_cons.
  × apply StronglySorted_remove. apply IHL. apply H.
  × apply Forall_remove. apply Forall_forall. rewrite Forall_forall in H0.
    intros x Hin. apply H0. apply nodup_cancel_in in Hin. auto.
+ apply StronglySorted_remove. apply IHL. apply H.

```

Qed.

An interesting side effect of the “cancelling” behavior of this function is that while the number of occurrences of an item may change after calling `nodup_cancel`, the evenness of the count never will. If an element was odd before there will be one occurrence, and if it was even before there will be none.

Lemma `count_occ_nodup_cancel` : $\forall \{A \text{ Aeq_dec} \} p (a:A),$
`even` (`count_occ` $\text{Aeq_dec } (\text{nodup_cancel } \text{Aeq_dec } p) a$) =
`even` (`count_occ` $\text{Aeq_dec } p a$).

Proof.

```

intros A Aeq_dec p a. induction p as [|b|]; auto. simpl.
destruct (even (count_occ Aeq_dec p b)) eqn:Hb.
- simpl. destruct (Aeq_dec b a).
  + rewrite e. rewrite count_occ_remove. rewrite e in Hb. repeat rewrite even_succ.
    rewrite ← negb_odd in Hb. rewrite Bool.negb_true_iff in Hb. rewrite Hb. auto.
  + rewrite count_occ_neq_remove; auto.
- simpl. destruct (Aeq_dec b a).
  + rewrite e. rewrite count_occ_remove. rewrite e in Hb. repeat rewrite even_succ.
    rewrite ← negb_odd in Hb. rewrite Bool.negb_false_iff in Hb. rewrite Hb. auto.
  + rewrite count_occ_neq_remove; auto.
Qed.

```

Permutation_nodup was challenging to prove before, and this version for nodup_cancel faces the same problems. The first and fourth cases are easy, and the second isn't too bad after using count_occ_Permutation. The third case faces the same problems as before, but requires some extra work when transitioning from reasoning about `count_occ (x::l) y` to `count_occ (y::l) x`.

This is accomplished by using `even_succ`, `negb_odd`, and `negb_true_iff`. In this way, we can convert something saying `even (S n) = true` to `even n = false`.

Lemma nodup_cancel_Permutation : $\forall (A:\text{Type}) \text{Aeq_dec } (l \text{ } l':\text{list } A),$
Permutation $l \text{ } l' \rightarrow$
Permutation (nodup_cancel Aeq_dec l) (nodup_cancel Aeq_dec l').

Proof.

```

intros A Aeq_dec l l' H. induction H.

  rewrite Hevx. rewrite e. auto.
+ rewrite Hevy. destruct (Aeq_dec y x); try (symmetry in e; contradiction).
  rewrite Hevx. rewrite remove_remove. auto.
- apply Permutation_trans with (l':=(nodup_cancel Aeq_dec l')); auto.
Qed.

```

As mentioned earlier, in the original definition of the function, it was helpful to reverse the order of `remove` and the recursive call to `nodup_cancel`. This is possible because these operations are associative, which is proven below.

Lemma `nodup_cancel_remove_assoc` : $\forall \{A\} \text{ Aeq_dec } (a:A) \text{ } p,$
`remove Aeq_dec a (nodup_cancel Aeq_dec p) =`
`nodup_cancel Aeq_dec (remove Aeq_dec a p).`

Proof.

```

intros A Aeq_dec a p. induction p.
- simpl. auto.
- simpl. destruct even eqn:Hevn.
  + simpl. destruct (Aeq_dec a a0).
    × rewrite ← e. rewrite not_in_remove; auto. apply remove_In.
    × simpl. rewrite count_occ_neq_remove; auto. rewrite Hevn.
      f_equal. rewrite ← IHp. rewrite remove_remove. auto.
  + destruct (Aeq_dec a a0).
    × rewrite ← e. rewrite not_in_remove; auto. apply remove_In.
    × simpl. rewrite count_occ_neq_remove; auto. rewrite Hevn.
      rewrite remove_remove. rewrite ← IHp. auto.

```

Qed.

The entire point of defining `nodup_cancel` was so that repeated elements in a list cancel out; clearly then, if an entire list appears twice it will cancel itself out. This proof would be much easier if the order of `remove` and `nodup_cancel` was swapped, but the above proof of the two being associative makes it easier to manage.

Lemma `nodup_cancel_self` : $\forall \{A\} \text{ Aeq_dec } (l:\text{list } A),$
`nodup_cancel Aeq_dec (l++l) = []`.

Proof.

```

intros A Aeq_dec p. induction p.

```

```

- auto.
- simpl. destruct even eqn:Hevn.
+ rewrite count_occ_app in Hevn. destruct (count_occ Aeq_dec p a) eqn:Hx.
  × simpl in Hevn. destruct (Aeq_dec a a); try contradiction.
  rewrite Hx in Hevn. inversion Hevn.
  × simpl in Hevn. destruct (Aeq_dec a a); try contradiction.

  simpl. auto.
+ clear Hevn. rewrite nodup_cancel_remove_assoc. rewrite remove_distr_app.
  simpl. destruct (Aeq_dec a a); try contradiction.
  rewrite ← remove_distr_app. rewrite ← nodup_cancel_remove_assoc.
  rewrite IHp. auto.

```

Qed.

Next up is a useful fact about `ln` that results from `nodup_cancel`. Because when there's an even number of an element they all get removed, we can say that there will not be any in the resulting list.

Lemma not_in_nodup_cancel : $\forall \{A \text{ Aeq_dec}\} (m:A) p,$
`even (count_occ Aeq_dec p m) = true →`
`¬ ln m (nodup_cancel Aeq_dec p).`

Proof.

```

intros A Aeq_dec m p H. induction p.
- simpl. auto.
- intro. simpl in H. destruct (Aeq_dec a m).
  + simpl in H0. rewrite even_succ in H. rewrite ← negb_even in H.
    rewrite Bool.negb_true_iff in H. rewrite ← e in H. rewrite H in H0.
    rewrite e in H0. apply remove_ln in H0. inversion H0.
  + apply IHp; auto. simpl in H0. destruct (even (count_occ Aeq_dec p a)).
    × destruct H0; try contradiction. apply ln_remove in H0. auto.
    × apply ln_remove in H0. auto.

```

Qed.

Similarly to the above lemma, because `a` will already be removed from `p` by `nodup_cancel`, whether or not a `remove` is added doesn't make a difference.

Lemma nodup_extra_remove : $\forall \{A \text{ Aeq_dec}\} (a:A) p,$
`even (count_occ Aeq_dec p a) = true →`
`nodup_cancel Aeq_dec p =`
`nodup_cancel Aeq_dec (remove Aeq_dec a p).`

Proof.

```

intros A Aeq_dec a p H. induction p as [|b]; auto. simpl.
destruct (Aeq_dec a b).
- rewrite e in H. simpl in H. destruct (Aeq_dec b b); try contradiction.
  rewrite even_succ in H. rewrite ← negb_even in H.
  rewrite Bool.negb_true_iff in H.
  rewrite H. rewrite nodup_cancel_remove_assoc. rewrite e. auto.
- simpl. destruct (even (count_occ Aeq_dec p b)) eqn:Hev.
  + rewrite count_occ_neq_remove; auto. rewrite Hev. f_equal.
    rewrite IHp. auto. simpl in H. destruct (Aeq_dec);
    try (symmetry in e; contradiction). auto.
  + rewrite count_occ_neq_remove; auto. rewrite Hev. f_equal.
    apply IHp. simpl in H. destruct (Aeq_dec b a);
    try (symmetry in e; contradiction). auto.

```

Qed.

Lastly, one of the toughest `nodup_cancel` lemmas. Similarly to `remove_pointless`, if `nodup_cancel` is going to be applied later, there is no need for it to be applied twice. This lemma proves to be very useful when proving that two different polynomials are equal, because, as we will see later, there are often repeated calls to `nodup_cancel` inside one another. This lemma makes it significantly easier to deal with, as we can remove the redundant `nodup_cancels`.

This proof proved to be challenging, mostly because it is hard to reason about the parity of the same element in two different lists. In the proof, we begin with induction over p , and then move to destructing the count of a in each list. The first case follows easily from the two even hypotheses, `count_occ_app`, and a couple other lemmas. The second case is almost exactly the same, except a is removed by `nodup_cancel` and never makes it out front, so the call to `perm_skip` is removed.

The third case, where a appears an odd number of times in p and an even number of times in q , is slightly different, but still solved relatively easily with the use of `nodup_extra_remove`. The fourth case is by far the hardest. We begin by asserting that, since the count of a in q is odd, there must be at least one, and therefore we can rewrite with `ln_split` to get q into the form of $l1 ++ a ++ l2$. We then assert that, since the count of a in q is odd, the count in $l1 ++ l2$, or q with one a removed, must surely be even. These facts, combined with `remove_distr_app`, `count_occ_app`, and `nodup_cancel_remove_assoc`, allow us to slowly but surely work a out to the front and eliminate it with `perm_skip`. All that is left to do at that point is to perform similar steps in the induction hypothesis, so that both IHp and our goal are in terms of $l1$ and $l2$. IHp is then used to finish the proof.

Lemma `nodup_cancel_pointless` : $\forall \{A \text{ Aeq_dec}\} (p \ q : \text{list } A),$
`Permutation` (`nodup_cancel Aeq_dec (nodup_cancel Aeq_dec p ++ q)`)
`(nodup_cancel Aeq_dec (p ++ q)).`

```

Qed.

This lemma is simply a reformalization of the above for convenience, which follows simply because of `Permutation_app_comm`.

Lemma `nodup_cancel_pointless_r` : $\forall \{A \text{ Aeq_dec}\} (p \ q : \text{list } A),$

`Permutation`

$(\text{nodup_cancel } Aeq_dec (p \ ++ \ \text{nodup_cancel } Aeq_dec \ q))$
 $(\text{nodup_cancel } Aeq_dec (p \ ++ \ q)).$

Proof.

```

intros A Aeq_dec p q. apply Permutation_trans with (l' := (nodup_cancel Aeq_dec (
  nodup_cancel Aeq_dec q ++ p))). apply nodup_cancel_Permutation.
apply Permutation_app_comm.
apply Permutation_sym. apply Permutation_trans with (l' := (nodup_cancel
  Aeq_dec (q ++ p))). apply nodup_cancel_Permutation.
apply Permutation_app_comm. apply Permutation_sym.
apply nodup_cancel_pointless.

```

Qed.

An interesting side effect of `nodup_cancel_pointless` is that now we can show that `nodup_cancel` almost “distributes” over `app`. More formally, to prove that the `nodup_cancel` of two lists appended together is a permutation of `nodup_cancel` applied to two other lists appended, it is sufficient to show that the first of each and the second of each are permutations after applying `nodup_cancel` to them individually.

Lemma `nodup_cancel_app_Permutation` : $\forall \{A \text{ Aeq_dec}\} (a \ b \ c \ d : \text{list } A),$

`Permutation` $(\text{nodup_cancel } Aeq_dec \ a) (\text{nodup_cancel } Aeq_dec \ b) \rightarrow$

`Permutation` $(\text{nodup_cancel } Aeq_dec \ c) (\text{nodup_cancel } Aeq_dec \ d) \rightarrow$

`Permutation` $(\text{nodup_cancel } Aeq_dec (a \ ++ \ c)) (\text{nodup_cancel } Aeq_dec (b \ ++ \ d)).$

Proof.

```

intros A Aeq_dec a b c d H H0. rewrite ← (nodup_cancel_pointless a),
← (nodup_cancel_pointless b), ← (nodup_cancel_pointless_r _ c),
← (nodup_cancel_pointless_r _ d). apply nodup_cancel_Permutation.
apply Permutation_app; auto.

```

Qed.

5.5 Comparing Parity of Lists: `parity_match`

The final major definition over lists we wrote is `parity_match`. `parity_match` is closely related to `nodup_cancel`, and allows us to make statements about lists being equal after applying `nodup_cancel` to them. Clearly, if an element appears an even number of times in both lists, then it won't appear at all after `nodup_cancel`, and if an element appears an odd number of times in both lists, then it will appear once after `nodup_cancel`. The ultimate goal of creating this definition is to prove a lemma that if the parity of two lists matches, they are permutations of each other after applying `nodup_cancel`.

The definition simply states that for all elements, the parity of the number of occurrences in each list is equal.

Definition `parity_match` $\{A\}$ Aeq_dec $(l\ m:\text{list } A) : \text{Prop} :=$
 $\forall x, \text{even } (\text{count_occ } Aeq_dec\ l\ x) = \text{even } (\text{count_occ } Aeq_dec\ m\ x).$

A useful lemma in working towards this proof is that if the count of every variable in a list is even, then there will be no variables in the resulting list. This is relatively easy to prove, as we have already proven `not_in_nodup_cancel` and can contradict away the other cases.

Lemma `even_nodup_cancel` : $\forall \{A\} Aeq_dec\ (p:\text{list } A),$
 $(\forall x, \text{even } (\text{count_occ } Aeq_dec\ p\ x) = \text{true}) \rightarrow$
 $(\forall x, \neg \text{In } x\ (\text{nodup_cancel } Aeq_dec\ p)).$

Proof.

```

intros A Aeq_dec p H m. intro. induction p.
- inversion H0.
- simpl in *. pose (H m) as H1. symmetry in H1. destruct (Aeq_dec a m).
  + symmetry in H1. rewrite ← e in H1. rewrite even_succ in H1. rewrite ←
negb_even in H1.
    rewrite Bool.negb_true_iff in H1. rewrite H1 in H0. rewrite e in H0.
    apply remove_In in H0. inversion H0.
  + destruct (even (count_occ Aeq_dec p a)).
    × destruct H0; try contradiction. apply ln_remove in H0. symmetry in H1.
      apply not_in_nodup_cancel in H1. contradiction.
    × apply ln_remove in H0. symmetry in H1. apply not_in_nodup_cancel in H1.
      contradiction.

```

Qed.

The above lemma can then be used in combination with `nothing_in_empty` to easily prove `parity_match_empty`, which will be useful in two cases of our goal lemma.

Lemma `parity_match_empty` : $\forall \{A\} Aeq_dec\ (q:\text{list } A),$
`parity_match` $Aeq_dec\ []\ q \rightarrow$
`Permutation` $[]\ (\text{nodup_cancel } Aeq_dec\ q).$

Proof.

```

intros A Aeq_dec q H. unfold parity_match in H. simpl in H.

```

symmetry in H . pose (even_nodup_cancel q H). apply nothing_in_empty in n .
 rewrite n . auto.

Qed.

The `parity_match` definition is also reflexive, symmetric, and transitive, and knowing this will make future proofs easier.

Lemma `parity_match_refl` : $\forall \{A \text{ Aeq_dec}\} (l : \text{list } A)$,
`parity_match Aeq_dec l l`.

Proof.

intros A Aeq_dec l . unfold `parity_match`. auto.

Qed.

Lemma `parity_match_sym` : $\forall \{A \text{ Aeq_dec}\} (l \ m : \text{list } A)$,
`parity_match Aeq_dec l m` \leftrightarrow `parity_match Aeq_dec m l`.

Proof.

intros l m . unfold `parity_match`. split; intros H x ; auto.

Qed.

Lemma `parity_match_trans` : $\forall \{A \text{ Aeq_dec}\} (p \ q \ r : \text{list } A)$,
`parity_match Aeq_dec p q` \rightarrow
`parity_match Aeq_dec q r` \rightarrow
`parity_match Aeq_dec p r`.

Proof.

intros A Aeq_dec p q r H $H0$. unfold `parity_match` in *. intros x .
 rewrite H . rewrite $H0$. auto.

Qed.

Hint Resolve `parity_match_refl` `parity_match_sym` `parity_match_trans`.

There are also a few interesting facts that can be proved about elements being consed onto lists in a `parity_match`. First is that if the parity of two lists is equal, then the parities will also be equal after adding another element to the front, and vice versa.

Lemma `parity_match_cons` : $\forall \{A \text{ Aeq_dec}\} (a : A) \ l1 \ l2$,
`parity_match Aeq_dec (a :: l1) (a :: l2)` \leftrightarrow
`parity_match Aeq_dec l1 l2`.

Proof.

intros A Aeq_dec a $l1$ $l2$. unfold `parity_match`. split; intros H x .
 - pose (H x). symmetry in e . simpl in e . destruct (Aeq_dec a x); auto.
 repeat rewrite `even_succ` in e . repeat rewrite \leftarrow `negb_even` in e .
 apply `Bool.negb_sym` in e . rewrite `Bool.negb_involutive` in e . auto.
 - simpl. destruct (Aeq_dec a x); auto.
 repeat rewrite `even_succ`. repeat rewrite \leftarrow `negb_even`.
 apply `Bool.negb_sym`. rewrite `Bool.negb_involutive`. auto.

Qed.

Similarly, adding the same element twice to a list does not change the parities of any elements in the list.

Lemma parity_match_double : $\forall \{A \text{ Aeq_dec}\} (a:A) l,$
 parity_match Aeq_dec (a :: a :: l) l.

Proof.

```
intros A Aeq_dec a l. unfold parity_match. intros x. simpl.
destruct (Aeq_dec a x).
- rewrite even_succ. rewrite odd_succ. auto.
- auto.
```

Qed.

The last cons parity_match lemma states that if you remove an element from one list and add it to the other, the parity will not be affected. This follows because if they both had an even number of a before they will both have an odd number after, and if it was odd before it will be even after.

Lemma parity_match_cons_swap : $\forall \{A \text{ Aeq_dec}\} (a:A) l1 l2,$
 parity_match Aeq_dec (a :: l1) l2 \rightarrow
 parity_match Aeq_dec l1 (a :: l2).

Proof.

```
intros A Aeq_dec a l1 l2 H. apply (parity_match_cons a) in H.
apply parity_match_sym in H. apply parity_match_trans with (r:=l1) in H.
apply parity_match_sym in H. auto. apply parity_match_double.
```

Qed.

This next lemma states that if we know that some element a appears in the *rest* of the list an even number of times, then clearly it appears in $l2$ an odd number of times and must be in the list.

Lemma parity_match_in : $\forall \{A \text{ Aeq_dec}\} (a:A) l1 l2,$
 even (count_occ Aeq_dec l1 a) = true \rightarrow
 parity_match Aeq_dec (a :: l1) l2 \rightarrow
 in a l2.

Proof.

```
intros A Aeq_dec a l1 l2 H H0. apply parity_match_cons_swap in H0.
rewrite H0 in H. simpl in H. destruct (Aeq_dec a a); try contradiction.
rewrite even_succ in H. rewrite <- negb_even in H. rewrite Bool.negb_true_iff in H.
assert (count_occ Aeq_dec l2 a > 0). destruct count_occ. inversion H.
apply gt_Sn_O. apply count_occ_in in H1. auto.
```

Qed.

The last fact to prove before attempting the big lemma is that if two lists are permutations of each other, then their parities must match because they contain the same elements the same number of times.

Lemma Permutation_parity_match : $\forall \{A \text{ Aeq_dec}\} (p \ q:\text{list } A),$
 Permutation p q \rightarrow parity_match Aeq_dec p q.

Proof.

```
intros A Aeq_dec p q H. induction H.
```

```

- auto.
- apply parity_match_cons. auto.
- repeat apply parity_match_cons_swap. unfold parity_match. intros x0.
  simpl. destruct Aeq_dec; destruct Aeq_dec;
  repeat (rewrite even_succ; rewrite odd_succ); auto.
- apply parity_match_trans with (q:=l'); auto.

```

Qed.

Finally, the big one. The first three cases are straightforward, especially now that we have already proven `parity_match_empty`. The third case is more complicated. We begin by destructing if a and $a0$ are equal. In the case that they are, the proof is relatively straightforward; `parity_match_cons`, `perm_skip`, and `remove_permutation` take care of it.

In the case that they are not equal, we next destruct if the number of occurrences is even or not. If it is odd, we can use `parity_match_in` and `in_split` to rewrite $l2$ in terms of a . From there, we use permutation facts to rearrange a to be at the front, and the rest of the proof is similar to the proof when a and $a0$ are equal.

The final case is when they are not equal and the number of occurrences is even. After using `parity_match_cons_swap`, we can get to a point where we know that a appears in $q++a0$ an even number of times. This means that a will not be in $q++a0$ after applying `nodup_cancel`, so we can rewrite with `not_in_remove` in the reverse direction to get the two sides of the permutation goal to be more similar. Then, because it is wrapped in `remove` a , we can clearly add an a on the inside without it having any effect. Then all that is left is to apply `remove_permutation`, and we end up with a goal matching the induction hypothesis.

This lemma is very powerful, especially when dealing with `nodup_cancel` with functions applied to the elements of a list. This will come into play later in this file.

Lemma `parity_nodup_cancel_permutation` : $\forall \{A \text{ Aeq_dec} \} (p \ q : \text{list } A),$
`parity_match Aeq_dec p q \rightarrow`
`Permutation (nodup_cancel Aeq_dec p) (nodup_cancel Aeq_dec q).`

Proof.

```

5.6 Combining nodup_cancel and Other Functions

5.6.1 Using nodup_cancel over map

Our next goal is to prove things about the relation between `nodup_cancel` and `map` over lists. In particular, we want to prove a lemma similar to `nodup_cancel_pointless`, that allows us to remove redundant `nodup_cancels`.

The challenging part of proving this lemma is that it is often hard to reason about how, for example, the number of times a appears in p relates to the number of times $f a$ appears in `map f p`. Many of the functions we map across lists in practice are not one-to-one, meaning that there could be some b such that $f a = f b$. However, at the end of the day, these repeated elements will cancel out with each other and the parities will match, hence why `parity_nodup_cancel Permutation` is extremely useful.

To begin, we need to prove a couple facts comparing the number of occurrences of elements in a list. The first lemma states that the number of times some a appears in p is less than

or equal to the number of times $f a$ appears in $\text{map } f p$.

Lemma `count_occ_map_lt` : $\forall \{A \text{ Aeq_dec}\} p (a:A) f,$
 $\text{count_occ } \text{Aeq_dec } p a \leq \text{count_occ } \text{Aeq_dec } (\text{map } f p) (f a).$

Proof.

```
intros A Aeq_dec p a f. induction p. auto. simpl. destruct Aeq_dec.
- rewrite e. destruct Aeq_dec; try contradiction. simpl. apply le_n_S. auto.
- destruct Aeq_dec; auto.
```

Qed.

Building off this idea, the next lemma states that the number of times $f a$ appears in $\text{map } f p$ with a removed is equal to the count of $f a$ in $\text{map } f p$ minus the count of a in p .

Lemma `count_occ_map_sub` : $\forall \{A \text{ Aeq_dec}\} f (a:A) p,$
 $\text{count_occ } \text{Aeq_dec } (\text{map } f (\text{remove } \text{Aeq_dec } a p)) (f a) =$
 $\text{count_occ } \text{Aeq_dec } (\text{map } f p) (f a) - \text{count_occ } \text{Aeq_dec } p a.$

Proof.

```
intros A Aeq_dec f a p. induction p; auto. simpl. destruct Aeq_dec.
- rewrite e. destruct Aeq_dec; try contradiction. destruct Aeq_dec;
  try contradiction. simpl. rewrite ← e. auto.
- simpl. destruct Aeq_dec.
  + destruct Aeq_dec. symmetry in e0; contradiction. rewrite IHp.
    rewrite sub_succ_l. auto. apply count_occ_map_lt.
  + destruct Aeq_dec. symmetry in e; contradiction. auto.
```

Qed.

It is also true that if there is some x that is *not* equal to $f a$, then the count of that x in $\text{map } f p$ is the same as the count of x in $\text{map } f p$ with a removed.

Lemma `count_occ_map_neq_remove` : $\forall \{A \text{ Aeq_dec}\} f (a:A) p x,$
 $x \neq (f a) \rightarrow$
 $\text{count_occ } \text{Aeq_dec } (\text{map } f (\text{remove } \text{Aeq_dec } a p)) x =$
 $\text{count_occ } \text{Aeq_dec } (\text{map } f p) x.$

Proof.

```
intros. induction p as [|b]; auto. simpl. destruct (Aeq_dec a b).
- destruct Aeq_dec. rewrite ← e in e0. symmetry in e0. contradiction.
  auto.
- simpl. destruct Aeq_dec; auto.
```

Qed.

The next lemma is similar to `count_occ_map_lt`, except it involves some b where a is not equal to b , but $f a = f b$. Then clearly, the sum of a in p and b in p is less than the count of $f a$ in $\text{map } f p$.

Lemma `f_equal_sum_lt` : $\forall \{A \text{ Aeq_dec}\} f (a:A) b p,$
 $b \neq a \rightarrow (f a) = (f b) \rightarrow$
 $\text{count_occ } \text{Aeq_dec } p b +$
 $\text{count_occ } \text{Aeq_dec } p a \leq$

`count_occ Aeq_dec (map f p) (f a).`

Proof.

```

intros A Aeq_dec f a b p Hne Hfe. induction p as [|c]; auto. simpl. destruct Aeq_dec.
- rewrite e. destruct Aeq_dec; try contradiction. rewrite Hfe.
  destruct Aeq_dec; try contradiction. simpl. apply le_n_S.
  rewrite ← Hfe. auto.
- destruct Aeq_dec.
  + rewrite e. destruct Aeq_dec; try contradiction. rewrite plus_comm.
    simpl. rewrite plus_comm. apply le_n_S. auto.
  + destruct Aeq_dec.
    × apply le_S. auto.
    × auto.

```

Qed.

For the next lemma, we once again try to compare the count of a to the count of $f a$, but also involve `nodup_cancel`. Clearly, there is no way for there to be more a 's in p than $f a$'s in `map f p` even with the addition of `nodup_cancel`.

Lemma `count_occ_nodup_map_lt` : $\forall \{A \text{ Aeq_dec}\} p f (a:A),$
`count_occ Aeq_dec (nodup_cancel Aeq_dec p) a ≤`
`count_occ Aeq_dec (map f (nodup_cancel Aeq_dec p)) (f a).`

Proof.

```

intros A Aeq_dec p f a. induction p as [|b]; auto. simpl. destruct even eqn:Hev.
- simpl. destruct Aeq_dec.
  + rewrite e. destruct Aeq_dec; try contradiction. apply le_n_S. auto.
    rewrite count_occ_remove. apply le_0_l.
  + rewrite count_occ_neq_remove; auto. rewrite not_in_remove.
    destruct Aeq_dec; firstorder. apply not_in_nodup_cancel; auto.
- destruct (Aeq_dec b a) eqn:Hba.
  + rewrite e. rewrite count_occ_remove. apply le_0_l.
  + rewrite count_occ_neq_remove; auto. destruct (Aeq_dec (f b) (f a)) eqn:Hfba.
    × rewrite ← e. rewrite count_occ_map_sub. rewrite e. apply le_add_le_sub_l.
      apply f_equal_sum_lt; auto.
    × rewrite count_occ_map_neq_remove; auto.

```

Qed.

All of these lemmas now come together for the core one, a variation of `nodup_cancel_pointless` but involving `map f`. We begin by applying `parity_nodup_cancel_permutation`, and destructing if a appears in p an even number of times or not.

The even case is relatively easy to prove, and only involves using the usual combination of `even_succ`, `not_in_remove`, and `not_in_nodup_cancel`.

The odd case is trickier, and where we involve all of the newly proved lemmas. If x and $f a$ are not equal, the proof follows just from `count_occ_map_neq_remove` and the induction hypothesis.

If they are equal, we begin by rewriting with `count_occ_map_sub` and `even_sub`. After a

few more rewrites, it becomes the case that we need to prove that the boolean equivalence of the parities of $f\ a$ in `map f p` and a in p is equal to the negated parity of $f\ a$ in `map f p`. Because we know that a appears in p an odd number of times from destructing `even` earlier, this follows immediately.

Lemma `nodup_cancel_map` : $\forall \{A\ Aeq_dec\} (p : \text{list } A) f,$

Permutation

$(\text{nodup_cancel } Aeq_dec (\text{map } f (\text{nodup_cancel } Aeq_dec p)))$
 $(\text{nodup_cancel } Aeq_dec (\text{map } f p)).$

Proof.

```

  + rewrite count_occ_map_neq_remove; auto.
```

Qed.

5.7 Using `nodup_cancel` over `concat map`

Similarly to `map`, the same property of not needing repeated `nodup_cancels` applies when the lists are being concatenated and mapped over. This final section of the file seeks to, in very much the same way as earlier, prove this.

We begin with a simple lemma about math that will come into play soon - if a number is less than or equal to 1, then it is either 0 or 1. This is immediately solved with firstorder logic.

Lemma `n_le_1` : $\forall n,$

$n \leq 1 \rightarrow n = 0 \vee n = 1.$

Proof.

```
intros n H. induction n; firstorder.
```

Qed.

The main difference between this section and the section about `map` is that all of the functions being mapped will clearly be returning lists as their output, and then being concatenated with the rest of the result. This makes things slightly harder, as we can't reason about the number of times, for example, some $f\ a$ appears in a list. Instead, we have to rea-

son about the number of times that some x appears in a list, where x is one of the elements of the list $f a$.

In practice, these lemmas are only going to be applied in situations where every $f a$ has no duplicates in it. In other words, as the lemma above states, there will be either 0 or 1 of each x in a list. The next two lemmas prove some consequences of this.

First is that if the count of x in $f a$ is 0, then clearly removing a from some list p will not affect the count of x in the concatenated version of the list.

Lemma `count_occ_map_sub_not_in` : $\forall \{A \text{ Aeq_dec}\} f (a:A) p,$
 $\forall x, \text{count_occ } \text{Aeq_dec} (f a) x = 0 \rightarrow$
 $\text{count_occ } \text{Aeq_dec} (\text{concat } (\text{map } f (\text{remove } \text{Aeq_dec } a p))) x =$
 $\text{count_occ } \text{Aeq_dec} (\text{concat } (\text{map } f p)) x.$

Proof.

```
intros A Aeq_dec f a p x H. induction p as [|b]; auto. simpl.
rewrite count_occ_app. destruct Aeq_dec.
- rewrite e in H. rewrite H. firstorder.
- simpl. rewrite count_occ_app. auto.
```

Qed.

On the other hand, if the count of some x in $f a$ is 1, then the count of a in the original list must be less than or equal to the count of x in the final list, depending on if some b exists such that $f a$ also contains x . More useful is the fact that if x appears once in $f x$, the count of x in the final list with a removed is equal to the count of x in the final list minus the count of a in the list. Both of these proofs are relatively straightforward, and mostly follow from firstorder logic.

Lemma `count_occ_concat_map_lt` : $\forall \{A \text{ Aeq_dec}\} p (a:A) f x,$
 $\text{count_occ } \text{Aeq_dec} (f a) x = 1 \rightarrow$
 $\text{count_occ } \text{Aeq_dec} p a \leq \text{count_occ } \text{Aeq_dec} (\text{concat } (\text{map } f p)) x.$

Proof.

```
intros A Aeq_dec p a f x H. induction p. auto. simpl. destruct Aeq_dec.
- rewrite e. rewrite count_occ_app. rewrite H. simpl. firstorder.
- rewrite count_occ_app. induction (count_occ Aeq_dec (f a0) x); firstorder.
```

Qed.

Lemma `count_occ_map_sub_in` : $\forall \{A \text{ Aeq_dec}\} f (a:A) p,$
 $\forall x, \text{count_occ } \text{Aeq_dec} (f a) x = 1 \rightarrow$
 $\text{count_occ } \text{Aeq_dec} (\text{concat } (\text{map } f (\text{remove } \text{Aeq_dec } a p))) x =$
 $\text{count_occ } \text{Aeq_dec} (\text{concat } (\text{map } f p)) x - \text{count_occ } \text{Aeq_dec} p a.$

Proof.

```
intros A Aeq_dec f a p x H. induction p as [|b]; auto. simpl. destruct Aeq_dec.
- rewrite e. destruct Aeq_dec; try contradiction. rewrite count_occ_app.
  rewrite e in H. rewrite H. simpl. rewrite ← e. auto.
- simpl. destruct Aeq_dec. symmetry in e. contradiction.
  repeat rewrite count_occ_app. rewrite IHp. rewrite add_sub_assoc. auto.
```

apply count_occ_concat_map_lt; auto.
Qed.

Continuing the pattern of proving similar facts as we did during the `map` proof, we now prove a version of `f_equal_sum_lt` involving `concat`. This lemma states that, if we know there will be no duplicates in $f\ x$ for all x , and that there are some a and b such that they are not equal but x is in both $f\ a$ and $f\ b$, then clearly the sum of the count of a and the count of b is less than or equal to the count of x in the list after applying the function and concatenating.

Lemma `f_equal_concat_sum_lt` : $\forall \{A\} \text{Aeq_dec} \{f\} (a:A) b\ p\ x,$
 $b \neq a \rightarrow$
 $(\forall x, \text{NoDup } (f\ x)) \rightarrow$
 $\text{count_occ } \text{Aeq_dec } (f\ a)\ x = 1 \rightarrow$
 $\text{count_occ } \text{Aeq_dec } (f\ b)\ x = 1 \rightarrow$
 $\text{count_occ } \text{Aeq_dec } p\ b +$
 $\text{count_occ } \text{Aeq_dec } p\ a \leq$
 $\text{count_occ } \text{Aeq_dec } (\text{concat } (\text{map } f\ p))\ x.$

Proof.

```
intros A Aeq_dec f a b p x Hne Hnd Hfa Hfb. induction p as [|c]; auto. simpl.
destruct Aeq_dec.
- rewrite e. destruct Aeq_dec; try contradiction. rewrite count_occ_app.
  firstorder.
- destruct Aeq_dec.
  + rewrite e. rewrite count_occ_app. firstorder.
  + rewrite count_occ_app. pose (Hnd c). rewrite (NoDup_count_occ Aeq_dec) in n1.
    pose (n1 x). apply n_le_1 in l. clear n1. destruct l; firstorder.
```

Qed.

The last step before we are able to prove `nodup_cancel_concat_map` is to actually involve `nodup_cancel` rather than just `remove`. This lemma states that given $f\ x$ has no duplicates and a appears once in $f\ a$, the count of a in p after applying `nodup_cancel` is less than or equal to the count of x after applying `concat map` and `nodup_cancel`.

The first cases, when the count is even, are relatively straightforward. The second cases, when the count is odd, are slightly more complicated. We destruct if a and b (where b is our induction element) are equal. If they are, then the proof is solved by firstorder logic. On the other hand, if they are not, we make use of our `n_le_1` fact proved before to find out how many times x appears in $f\ b$. If it is zero, then we rewrite with the 0 fact proved earlier and are done. In the final case, we rewrite with the 1 subtraction fact we proved earlier, and it follows from `f_equal_concat_sum_lt`.

Lemma `count_occ_nodup_concat_map_lt` : $\forall \{A\} \text{Aeq_dec} \{p\} f\ (a:A) x,$
 $(\forall x, \text{NoDup } (f\ x)) \rightarrow$
 $\text{count_occ } \text{Aeq_dec } (f\ a)\ x = 1 \rightarrow$
 $\text{count_occ } \text{Aeq_dec } (\text{nodup_cancel } \text{Aeq_dec } p)\ a \leq$

`count_occ Aeq_dec (concat (map f (nodup_cancel Aeq_dec p))) x.`

Proof.

`intros A Aeq_dec p f a x Hn H. induction p as [|b]; auto. simpl. destruct even eqn:Hev.`

`- simpl. destruct Aeq_dec.
 + rewrite e. rewrite count_occ_remove, count_occ_app. rewrite H. firstorder.
 + rewrite count_occ_neq_remove; auto. rewrite not_in_remove.
 rewrite count_occ_app. firstorder. apply not_in_nodup_cancel. auto.
- destruct (Aeq_dec b a) eqn:Hba.
 + rewrite e. rewrite count_occ_remove. firstorder.
 + rewrite count_occ_neq_remove; auto. assert (Hn1:=(Hn b)).
 rewrite (NoDup_count_occ Aeq_dec) in Hn1. assert (Hn2:=(Hn1 x)).
 clear Hn1. apply n_le_1 in Hn2. destruct Hn2.
 × rewrite count_occ_map_sub_not_in; auto.
 × apply (count_occ_map_sub_in _ _ (nodup_cancel Aeq_dec p)) in H0 as H1.
 rewrite H1. apply le_add_le_sub_l. apply f_equal_concat_sum_lt; auto.`

Qed.

Finally, the proof we've been building up to. Once again, we begin the proof by converting to a `parity_match` problem and then perform induction on the list. The case where a appears an even number of times in the list is easy, and follows from the same combination of `count_occ_app` and `even_add` that we have used before.

The case where a appears an odd number of times is slightly more complex. Once again, we apply `n_le_1` to determine how many times our x appears in $f a$. If it is zero times, we use `count_occ_map_sub_not_in` like above, and then the induction hypothesis solves it. If x appears once in $f a$, we instead use `count_occ_map_sub_in` combined with `even_sub`. Then, after rewriting with the induction hypothesis, we can easily solve the lemma with the use of `count_occ_nodup_cancel`.

Lemma `nodup_cancel_concat_map` : $\forall \{A \text{ Aeq_dec}\} (p:\text{list } A) f,$

$(\forall x, \text{NoDup } (f x)) \rightarrow$

Permutation

$(\text{nodup_cancel } Aeq_dec (\text{concat } (\text{map } f (\text{nodup_cancel } Aeq_dec p))))$
 $(\text{nodup_cancel } Aeq_dec (\text{concat } (\text{map } f p))).$

Proof.

`intros A Aeq_dec p f H. apply parity_nodup_cancel_Permutation. unfold parity_match.

6.1 Monomials and Polynomials

6.1.1 Data Type Definitions

A monomial is simply a list of variables, with variables as defined in terms.v.

Definition mono := list var.

Definition mono_eq_dec := (list_eq_dec Nat.eq_dec).

A polynomial, then, is a list of monomials.

Definition poly := list mono.

6.1.2 Comparisons of monomials and polynomials

Definition mono_cmp := lex compare.

Definition mono_lt $m\ n$:= mono_cmp $m\ n$ = Lt.

6.1.3 Stronger Definitions

Because as far as Coq is concerned any list of natural numbers is a monomial, it is necessary to define a few more predicates about monomials and polynomials to ensure our desired properties hold. Using these in proofs will prevent any random list from being used as a monomial or polynomial.

Monomials are simply sorted lists of natural numbers.

Definition `is_mono` ($m : \text{mono}$) : Prop := **Sorted lt** m .

Polynomials are sorted lists of lists, where all of the lists in the polynomial are monomials.

Definition `is_poly` ($p : \text{poly}$) : Prop :=
Sorted `mono_lt` $p \wedge \forall m, \text{In } m \text{ } p \rightarrow \text{is_mono } m$.

Hint Unfold `is_mono` `is_poly`.

Hint Resolve `NoDup_cons` `NoDup_nil` `Sorted_cons`.

Definition `vars` ($p : \text{poly}$) : **list** var :=
nodup `var_eq_dec` (**concat** p).

Hint Unfold `vars`.

Lemma `NoDup_vars` : $\forall (p : \text{poly})$,
NoDup (`vars` p).

Proof.

intros p . unfold `vars`. apply **NoDup_nodup**.

Qed.

Lemma `in_mono_in_vars` : $\forall x \text{ } p$,
 $(\forall m : \text{mono}, \text{In } m \text{ } p \rightarrow \neg \text{In } x \text{ } m) \leftrightarrow \neg \text{In } x \text{ } (\text{vars } p)$.

Proof.

× auto.

Qed.

There are a few useful things we can prove about these definitions too. First, every element in a monomial is guaranteed to be less than the elements after it.

```
Lemma mono_order : ∀ x y m,
  is_mono (x :: y :: m) →
    x < y.
```

Proof.

```
  unfold is_mono.
  intros x y m H.
  apply Sorted_inv in H as [].
  apply HdRel_inv in H0.
  apply H0.
```

Qed.

Similarly, if $x :: m$ is a monomial, then m is also a monomial.

```
Lemma mono_cons : ∀ x m,
  is_mono (x :: m) →
    is_mono m.
```

Proof.

```
  unfold is_mono.
  intros x m H. apply Sorted_inv in H as []. apply H.
```

Qed.

The same properties hold for `is_poly` as well; any list in a polynomial is guaranteed to be less than the lists after it.

```
Lemma poly_order : ∀ m n p,
  is_poly (m :: n :: p) →
    mono_lt m n.
```

Proof.

```
  unfold is_poly.
  intros.
  destruct H.
  apply Sorted_inv in H as [].
  apply HdRel_inv in H1.
  apply H1.
```

Qed.

And if $m :: p$ is a polynomial, we know both that p is a polynomial and that m is a monomial.

```
Lemma poly_cons : ∀ m p,
  is_poly (m :: p) →
    is_poly p ∧ is_mono m.
```

Proof.

```
  unfold is_poly.
  intros.
```

```

7.1 Introduction

This section deals with defining substitutions and their properties using a polynomial representation. As with the inductive term representation, substitutions are just list of replacements, where variables are swapped with polynomials instead of terms. Crucial to the proof of correctness in the following chapter, substitution is proven to distribute over polynomial addition and multiplication. Definitions are provided for unifier, unifiable, and properties relating multiple substitutions such as more general and composition.

7.2 Substitution Definitions

A *substitution* is defined as a list of replacements. A *replacement* is just a tuple of a variable and a polynomial.

Definition repl := **prod** var poly.

Definition subst := **list** repl.

Since the *poly* data type doesn't enforce the properties of actual polynomials, the *is_poly* predicate is used to check if a term is in polynomial form. Likewise, the *is_poly_subst* predicate below verifies that every term in the range of the substitution is a polynomial.

Definition is_poly_subst (s : subst) : Prop :=
 $\forall x\ p, \text{In}(x, p) \rightarrow \text{is_poly } p.$

The next three functions implement how substitutions are applied to terms. At the top level, *substP* applies a substitution to a polynomial by calling *substM* on each monomial. From there, *substV* is called on each variable. Because variables and monomials are converted to polynomials, the process isn't simply mapping application across the lists. *substM* and *substP* must multiply and add each polynomial together respectively.

```
Fixpoint substV (s : subst) (x : var) : poly :=
  match s with
  | [] => [[x]]
  | (y, p) :: s' => if (x =? y) then p else (substV s' x)
  end.
```

```
Fixpoint substM (s : subst) (m : mono) : poly :=
  match m with
  | [] => [[]]
  | x :: m => mulPP (substV s x) (substM s m)
  end.
```

```
Definition substP (s : subst) (p : poly) : poly :=
  make_poly (concat (map (substM s) p)).
```

Useful in later proofs is the ability to rewrite the unfolded definition of *substP* as just the function call.

```
Lemma substP_refold : ∀ s p,
  make_poly (concat (map (substM s) p)) = substP s p.
```

Proof. auto. Qed.

The following lemmas state that substitution applications always produce polynomials. This fact is necessary for proving distribution and other properties of substitutions.

```
Lemma substV_is_poly : ∀ x s,
  is_poly_subst s →
  is_poly (substV s x).
```

Proof.

```
  intros x s H. unfold is_poly_subst in H. induction s; simpl; auto.
  destruct a eqn:Ha. destruct (x =? v).
  - apply (H v). intuition.
  - apply IHs. intros x0 p0 H0. apply (H x0). intuition.
```

Qed.

```
Lemma substM_is_poly : ∀ s m,
  is_poly (substM s m).
```

Proof.

```
  intros s m. unfold substM; destruct m; auto.
```

Qed.

```
Lemma substP_is_poly : ∀ s p,
  is_poly (substP s p).
```

Proof.

```
intros. unfold substP. auto.
```

Qed.

Hint Resolve *substP_is_poly substM_is_poly*.

The lemma below states that a substitution applied to a variable in polynomial form is equivalent to the substitution applied to just the variable. This fact only holds when the substitution's domain consists of polynomials.

```
Lemma subst_var_eq : ∀ x s,  
  is_poly_subst s →  
  substP s [[x]] = substV s x.
```

Proof.

```
intros. simpl.  
apply (substV_is_poly x s) in H. unfold substP. simpl. rewrite app_nil_r.  
rewrite mulPP_1r; auto. rewrite no_make_poly; auto.
```

Qed.

The next two lemmas deal with simplifying substitutions where the first replacement tuple is useless for the given term. This is the case when the variable being replaced is not present in the term. It allows the replacement to be dropped from the substitution without changing the result.

```
Lemma substM_cons : ∀ x m,  
  ¬ ln x m →  
  ∀ p s, substM ((x, p) :: s) m = substM s m.
```

Proof.

  rewrite ← make_poly_pointless_r. rewrite substP_refold.
  rewrite IHp; auto. rewrite empty_substM; auto.
  apply addPP_poly_cons; auto.
Qed.

```

7.3 Distribution Over Arithmetic Operators

Below is the statement and proof that substitution distributes over polynomial addition. Given a substitution s and two terms in polynomial form p and q , it is shown that $s(p + q) = s(p) + s(q)$. The proof relies heavily on facts about permutations proven in the *list_util* library.

```

Lemma substP_distr_addPP : ∀ p q s,
  is_poly p →
  is_poly q →
  substP s (addPP p q) = addPP (substP s p) (substP s q).
Proof.

```

```

intros p q s Hp Hq. unfold substP, addPP.
apply Permutation_sort_eq. apply Permutation_trans with (l':=
  (nodup_cancel mono_eq_dec (map make_mono (concat (map (substM s)
    (nodup_cancel mono_eq_dec (map make_mono (p ++ q)))))))).

  apply substM_is_poly.
intros m Hin. apply (substM_is_poly s x); auto.
intros m Hin. apply in_app_iff in Hin as []; destruct Hp; destruct Hq; auto.
intros m Hin. apply in_app_iff in Hin as []; apply nodup_cancel_in in H;
  apply mono_in_map_make_mono in H; auto.
Qed.

```

The next six lemmas deal with proving that substitution distributes over polynomial multiplication. Given a substitution s and two terms in polynomial form p and q , it is shown that $s(p \times q) = s(p) \times s(q)$. The proof turns out to be much more difficult than the one for addition because the underlying arithmetic operation is more complex.

If two monomials are permutations (obviously not in monomial form), then applying any substitution to either will produce the same result. A weaker form that follows from this is that the results are permutations as well.

Lemma `substM_Permutation_eq` : $\forall s \ m \ n$,

Permutation $m \ n \rightarrow$

substM s m = substM s n .

Proof.

```
intros s m n H. induction H; auto.
- simpl. rewrite IHPermutation. auto.
- simpl. rewrite mulPP_comm. rewrite mulPP_assoc.
  rewrite (mulPP_comm (substM s l)). auto.
- rewrite IHPermutation1. rewrite IHPermutation2. auto.
```

Qed.

Lemma substM_Permutation : $\forall s m n$,

Permutation $m n \rightarrow$
Permutation (substM $s m$) (substM $s n$).

Proof.

```
intros s m n H. rewrite (substM_Permutation_eq s m n); auto.
```

Qed.

Adding duplicate variables to a monomial doesn't change the result of applying a substitution. This is only true if the substitution's domain only has polynomials.

Lemma substM_nodup_pointless : $\forall s m$,

is_poly_subst $s \rightarrow$
 substM s (nodup var_eq_dec m) = substM $s m$.

Proof.

```
intros s m Hps. induction m; auto. simpl. destruct in_dec.
- apply in_split in i. destruct i as [l1 [l2 H]].
  assert (Permutation  $m (a :: l1 ++ l2)$ ). rewrite H. apply Permutation_sym.
  apply Permutation_middle.
  apply substM_Permutation_eq with (s:=s) in H0. rewrite H0. simpl.
  rewrite (mulPP_comm _ (substM _ _)). rewrite mulPP_comm.
  rewrite mulPP_assoc. rewrite mulPP_p_p. rewrite mulPP_comm. rewrite IHm.
  rewrite H0. simpl. auto. apply substV_is_poly. auto.
- simpl. rewrite IHm. auto.
```

Qed.

The idea behind the following two lemmas is that substitutions distribute over multiplication of a monomial and polynomial. The specifics of both are convoluted yet easier to prove than distribution over two polynomials.

Lemma substM_distr_mulMP : $\forall m n s$,

is_poly_subst $s \rightarrow$
 is_mono $n \rightarrow$
Permutation

```

Here is the formulation of substitution distributing over polynomial multiplication. Similar to the proof for addition, it is very dense and makes common use of permutation facts. Where it differs from that proof is that it relies on the commutativity of multiplication. The proof of distribution over addition didn't need any properties of addition.

Lemma substP_distr_mulPP : $\forall p \ q \ s,$
 $\text{is_poly_subst } s \rightarrow$

7.4 Unifiable Definitions

The following six definitions are all predicate functions that verify some property about substitutions or polynomials.

A *unifier* for a given polynomial p is a substitution s such that $s(p) = 0$. This definition also includes that the domain of the substitution only contain terms in polynomial form.

Definition `unifier` ($s : \text{subst}$) ($p : \text{poly}$) : `Prop` :=
`is_poly_subst s ∧ substP s p = []`.

A polynomial p is *unifiable* if there exists a unifier for p .

Definition `unifiable` ($p : \text{poly}$) : `Prop` :=
`∃ s, unifier s p`.

A substitution u is a composition of two substitutions s and t if $u(x) = t(s(x))$ for every variable x . The lemma *subst_comp_poly* below extends this definition from variables to polynomials.

Definition `subst_comp` ($s t u : \text{subst}$) : `Prop` :=
 $\forall x,$
`substP t (substP s [[x]]) = substP u [[x]]`.

A substitution s is *more general* than a substitution t if there exists a third substitution u such that t is a composition of u and s .

Definition `more_general` ($s t : \text{subst}$) : `Prop` :=
`∃ u, subst_comp s u t`.

Given a polynomial p , a substitution s is the *most general unifier* of p if s is more general than every unifier of p .

Definition `mgu` ($s : \text{subst}$) ($p : \text{poly}$) : `Prop` :=
`unifier s p ∧`
 $\forall t,$
`unifier t p →`
`more_general s t`.

Given a polynomial p , a substitution s is a *reproductive unifier* of p if t is a composition of itself and s for every unifier t of p . This property is similar but stronger than most general because the substitution that composes with s is restricted to t , whereas in most general it can be any substitution.

Definition `reprod_unif` ($s : \text{subst}$) ($p : \text{poly}$) : `Prop` :=
`unifier s p ∧`

$\forall t,$
 $\text{unifier } t \ p \rightarrow$
 $\text{subst_comp } s \ t \ t.$

Because the notion of most general is weaker than reproductive, it can be proven to logically follow as shown below. Any unifier that is reproductive is also most general.

Lemma `reprod_is_mgu` : $\forall p \ s,$
 $\text{reprod_unif } s \ p \rightarrow$
 $\text{mgu } s \ p.$

Proof.

`unfold mgu, reprod_unif, more_general, subst_comp.`
`intros p s [].`
`split; auto.`
`intros.`
 `$\exists t0.$`
`intros.`
`apply H0; auto.`

Qed.

As stated earlier, substitution composition can be extended to polynomials. This comes from the implicit fact that if two substitutions agree on all variables then they agree on all terms.

Lemma `subst_comp_poly` : $\forall s \ t \ u,$
 $\text{is_poly_subst } s \rightarrow$
 $\text{is_poly_subst } t \rightarrow$
 $\text{is_poly_subst } u \rightarrow$
 $(\forall x, \text{substP } t \ (\text{substP } s \ [[x]])) = \text{substP } u \ [[x]] \rightarrow$
 $\forall p,$
 $\text{substP } t \ (\text{substP } s \ p) = \text{substP } u \ p.$

Proof.

`intros. induction p; auto. simpl. unfold substP at 2. simpl.`
`rewrite \leftarrow make_poly_pointless_r. rewrite addPP_refold.`
`rewrite substP_distr_addPP; auto. unfold substP at 3. simpl.`
`rewrite \leftarrow make_poly_pointless_r. rewrite addPP_refold. f_equal.`
`- induction a; auto. simpl. rewrite substP_distr_mulPP; auto. f_equal; auto.`
`+ rewrite \leftarrow subst_var_eq; auto. rewrite \leftarrow subst_var_eq; auto.`
`+ apply substV_is_poly; auto.`
`- rewrite substP_refold. apply IHp.`

Qed.

The last lemmas of this section state that the identity substitution is a reproductive unifier of the constant zero. Therefore it is also most general.

Lemma `empty_unifier` : $\text{unifier } [] \ [].$

Proof.

```
    unfold unifier, is_poly_subst. split; auto.
    intros. inversion H.
```

Qed.

Lemma empty_reprod_unif : reprod_unif [] [].

Proof.

```
    unfold reprod_unif, more_general, subst_comp.
    split; auto. apply empty_unifier.
```

Qed.

Lemma empty_mgu : mgu [] [].

8.1 Introduction

Here we implement the algorithm for successive variable elimination. The basic idea is to remove a variable from the problem, solve that simpler problem, and build a solution from the simpler solution. The algorithm is recursive, so variables are removed and problems are generated until we are left with either of two problems; $1 \stackrel{?}{\approx}_B 0$ or $0 \stackrel{?}{\approx}_B 0$. In the former case, the whole original problem is not unifiable. In the latter case, the problem is solved without any need to substitute since there are no variables. From here, we begin the process of building up substitutions until we reach the original problem.

8.2 Eliminating Variables

This section deals with the problem of removing a variable x from a term t . The first thing to notice is that t can be written in polynomial form $t \downarrow_P$. This polynomial is just a set of monomials, and each monomial a set of variables. We can now separate the polynomials into two sets qx and r . The term qx will be the set of monomials in $t \downarrow_P$ that contain the variable x . The term q , or the quotient, is qx with the x removed from each monomial. The term r , or the remainder, will be the monomials in $t \downarrow_P$ that do not contain x . The original term can then be written as $x * q + r$.

Implementing this procedure is pretty straightforward. We define a function `div_by_var` that produces two polynomials given a polynomial p and a variable x to eliminate from it.

The first step is dividing p into qx and r which is performed using a partition over p with the predicate `has_var`. The second step is to remove x from qx using the helper `elim_var`.

The function `has_var` determines whether a variable appears in a monomial.

Definition `has_var` ($x : \text{var}$) := `existsb (beq_nat x)`.

The function `elim_var` removes a variable from each monomial in a polynomial. It is possible that this leaves the term not in polynomial form so it is then repaired with `make_poly`.

Definition `elim_var` ($x : \text{var}$) ($p : \text{poly}$) : `poly` :=
`make_poly (map (remove var_eq_dec x) p)`.

The function `div_by_var` produces a quotient q and remainder r from a polynomial p and variable x such that $p \approx_B x * q + r$ and x does not occur in r .

Definition `div_by_var` ($x : \text{var}$) ($p : \text{poly}$) : `prod poly poly` :=
`let (qx, r) := partition (has_var x) p in`
`(elim_var x qx, r)`.

We would also like to prove some lemmas about variable elimination that will be helpful in proving the full algorithm correct later. The main lemma below is `div_eq`, which just asserts that after eliminating x from p into q and r the term can be put back together as in $p \approx_B x * q + r$. This fact turns out to be rather hard to prove and needs the help of 10 or so other subsidiary lemmas.

After eliminating a variable x from a polynomial to produce r , x does not occur in r .

Lemma `elim_var_not_in_rem` : $\forall x p r$,
`elim_var x p = r` \rightarrow
`($\forall m$, ln m r \rightarrow \neg ln x m).`

Proof.

```

intros.
unfold elim_var in H.
unfold make_poly in H.
rewrite  $\leftarrow$  H in H0.
apply ln_sorted in H0.
apply nodup_cancel_in in H0.
rewrite map_map in H0.
apply in_map_iff in H0 as [n []].
rewrite  $\leftarrow$  H0.
intro.
rewrite make_mono_ln in H2.
apply remove_ln in H2.
auto.

```

Qed.

Eliminating a variable from a polynomial produces a term in polynomial form.

Lemma `elim_var_is_poly` : $\forall x p$,
`is_poly (elim_var x p)`.

Proof.

```
intros.
unfold elim_var.
apply make_poly_is_poly.
```

Qed.

Hint Resolve *elim_var_is_poly*.

The next four lemmas deal with the following scenario: Let p be a term in polynomial form, x be a variable that occurs in each monomial of p , and $r = \text{elim_var } x \ p$.

The term r is a permutation of removing x from p . Another way of looking at this statement is when elim_var repairs the term produced from removing a variable it only sorts that term.

Lemma `elim_var_map_remove_Permutation` : $\forall p \ x$,
`is_poly p →`
`($\forall m, \text{In } m \ p \rightarrow \text{In } x \ m$) →`
`Permutation (elim_var x p) (map (remove var_eq_dec x) p).`

Proof.

```
intros p x H H0. destruct p as [|a p].
- simpl. unfold elim_var, make_poly, MonoSort.sort. auto.
- simpl. unfold elim_var. simpl. unfold make_poly.
  rewrite ← Permutation_MonoSort_l. rewrite unsorted_poly; auto.
  + rewrite ← map_cons. apply NoDup_map_remove; auto.
  + apply poly_cons in H. intros m Hin. destruct Hin.
    × rewrite ← H1. apply remove_is_mono. apply H.
    × apply in_map_iff in H1 as [y []]. rewrite ← H1. apply remove_is_mono.
      destruct H. unfold is_poly in H. destruct H. apply H4. auto.
```

Qed.

The term $(x * r) \downarrow_P$ is a permutation of the result of removing x from p , appending x to the end of each monomial, and repairing each monomial. The proof relies on the `mulPP_map_app_permutation` lemma from the `poly` library, which has a simpler goal but does much of the heavy lifting.

Lemma `rebuild_map_permutation` : $\forall p \ x$,
`is_poly p →`
`($\forall m, \text{In } m \ p \rightarrow \text{In } x \ m$) →`
`Permutation (mulPP [[x]] (elim_var x p))`
`(map (fun a ⇒ make_mono (a ++ [x]))`
`(map (remove var_eq_dec x) p)).`

Proof.

```
intros p x H H0. apply mulPP_map_app_permutation; auto.
- apply (elim_var_not_in_rem x p); auto.
- apply elim_var_map_remove_Permutation; auto.
```

Qed.

The term p is a permutation of $(x * r) \downarrow_P$. Proof of this fact relies on the lengthy `map_app_remove_Permutation` lemma from `poly`.

```
Lemma elim_var_permutation : ∀ p x,
  is_poly p →
  (∀ m, In m p → In x m) →
  Permutation p (mulPP [[x]] (elim_var x p)).
```

Proof.

```
intros p x H H0. pose (rebuild_map_permutation p x H H0).
apply Permutation_sym in p0.
pose (map_app_remove_Permutation p x H H0).
apply (Permutation_trans p1 p0).
```

Qed.

Finally, $p = (x * r) \downarrow_P$.

```
Lemma elim_var_mul : ∀ x p,
  is_poly p →
  (∀ m, In m p → In x m) →
  p = mulPP [[x]] (elim_var x p).
```

Proof.

```
intros. apply Permutation_Sorted_eq.
- apply elim_var_permutation; auto.
- unfold is_poly in H. apply Sorted_MonoSorted. apply H.
- pose (mulPP_is_poly [[x]] (elim_var x p)). unfold is_poly in i.
  apply Sorted_MonoSorted. apply i.
```

Qed.

The function `has_var` is an equivalent boolean version of the `In` predicate.

```
Lemma has_var_eq_in : ∀ x m,
  has_var x m = true ↔ In x m.
```

Proof.

```
intros.
unfold has_var.
rewrite existsb_exists.
split; intros.
- destruct H as [x0 []].
  apply Nat.eqb_eq in H0.
  rewrite H0. apply H.
- ∃ x. rewrite Nat.eqb_eq. auto.
```

Qed.

Let a polynomial p be partitioned by `has_var x` into two sets qx and r . Obviously, every monomial in qx contains x and no monomial in r contains x .

```
Lemma part_var_eq_in : ∀ x p qx r,
  partition (has_var x) p = (qx, r) →
```

$((\forall m, \text{In } m \text{ } qx \rightarrow \text{In } x \text{ } m) \wedge$
 $(\forall m, \text{In } m \text{ } r \rightarrow \neg \text{In } x \text{ } m)).$

Proof.

```
intros.
split; intros.
- apply partfsttrue with (a:=m) in H.
  + apply has_var_eq_in. apply H.
  + apply H0.
- apply partsndfalse with (a:=m) in H.
  + rewrite ← has_var_eq_in. rewrite H. auto.
  + apply H0.
```

Qed.

The function `div_by_var` produces two terms both in polynomial form.

Lemma `div_is_poly` : $\forall x \text{ } p \text{ } q \text{ } r,$
 $\text{is_poly } p \rightarrow$
 $\text{div_by_var } x \text{ } p = (q, r) \rightarrow$
 $\text{is_poly } q \wedge \text{is_poly } r.$

Proof.

```
intros.
unfold div_by_var in H0.
destruct (partition (has_var x) p) eqn:Hpart.
apply (part_is_poly _ _ _ H) in Hpart as Hp.
destruct Hp as [Hpl Hpr].

Qed.

Hint Resolve div_vars.

8.3 Building Substitutions

This section handles how a solution is built from subproblem solutions. Given that term p decomposed into $(x * q + r) \downarrow_P$ and $p' = ((q + 1) * r) \downarrow_P$, the lemma `reprod_build_subst` states that if some substitution σ is a reproductive unifier of $p' \stackrel{?}{\approx}_B 0$, then we can build a substitution σ' which is a reproductive unifier of $p \stackrel{?}{\approx}_B 0$. The way σ' is built from σ is defined in `build_subst`. Another replacement is added to σ of the form $\{x \mapsto (x * (\sigma(q) + 1) + \sigma(r)) \downarrow_P\}$ to construct σ' .

```
Definition build_subst (s : subst) (x : var) (q r : poly) : subst :=
  let q1 := addPP [[]] q in
  let q1s := substP s q1 in
  let rs := substP s r in
  let xs := (x, addPP (mulPP [[]] q1s) rs) in
  xs :: s.
```

The function `build_subst` produces a substitution whose domain only contains polynomials.

```
Lemma build_subst_is_poly : ∀ s x q r,
  is_poly_subst s →
  is_poly_subst (build_subst s x q r).
```

Proof.

```
  unfold build_subst.

8.4 Recursive Algorithm

Now we define the actual algorithm of successive variable elimination. Built using five helper functions, the definition is not too difficult to construct or understand. The general idea, as mentioned before, is to remove one variable at a time, creating simpler problems. Once the simplest problem has been reached, to which the solution is already known, every solution to each subproblem can be built from the solution to the successive subproblem. Formally, given the polynomials $p = (x*q+r) \downarrow_P$ and $p' = ((q+1)*r) \downarrow_P$, the solution to $p \stackrel{?}{\approx}_B 0$ is built from the solution to $p' \stackrel{?}{\approx}_B 0$. If σ solves $p' \stackrel{?}{\approx}_B 0$, then $\sigma \cup \{x \mapsto (x * (\sigma(q) + 1) + \sigma(r)) \downarrow_P\}$ solves $p \stackrel{?}{\approx}_B 0$.

The function `sve` is the final result, but it is `sveVars` which actually has all of the meat. Due to Coq's rigid type system, every recursive function must be obviously terminating. This means that one of the arguments must decrease with each nested call. It turns out that Coq's type checker is unable to deduce that continually building polynomials from the quotient and remainder of previous ones will eventually result in 0 or 1. So instead we add a fuel argument that explicitly decreases per recursive call. We use the set of variables in the polynomial for this purpose, since each subsequent call has at least one less variable.

```
Fixpoint sveVars (varlist : list var) (p : poly) : option subst :=
  match varlist with
  | [] =>
    match p with
    | [] => Some []
    | _ => None
    end
  | x :: xs =>
    let (q, r) := div_by_var x p in
    let p' := (build_poly q r) in
    match sveVars xs p' with
    | None => None
    | Some s => Some (build_subst s x q r)
    end
  end.
```

The function `sve` simply calls `sveVars` with an initial fuel of `vars p`.

Definition `sve (p : poly) : option subst := sveVars (vars p) p`.

8.5 Correctness

Finally, we must show that this algorithm is correct. As discussed in the beginning, the correctness of a unification algorithm is proven for two cases. If the algorithm produces a solution for a problem, then the solution must be most general. If the algorithm produces no solution, then the problem must be not unifiable. These statements have been formalized in the theorem `sve_correct` with the help of the predicates `mg_u` and `unifiable` as defined in the library `poly_unif`. The two cases of the proof are handled separately by the lemmas `sveVars_some` and `sveVars_none`.

If `sveVars` produces a substitution σ , then the domain of σ only contains polynomials.

Lemma `sveVars_poly_subst` : $\forall xs\ p,$

```
incl (vars p) xs →
is_poly p →
 $\forall s,$  sveVars xs p = Some s →
is_poly_subst s.
```

Proof.

```
induction xs as [|x xs]; intros.
- simpl in H1. destruct p; inversion H1. unfold is_poly_subst.
  intros x p [].
- intros.
  assert ( $\exists qr,$  div_by_var x p = qr) as [|q r] Hqr. eauto.
  simpl in H1.
  rewrite Hqr in H1.
  destruct (sveVars xs (build_poly q r)) eqn:Hs0; inversion H1.
  apply IHxs in Hs0; eauto.
  apply build_subst_is_poly; auto.
```

Qed.

If `sveVars` produces a substitution σ for the polynomial p , then σ is a most general unifier of $p \approx_B 0$.

Lemma `sveVars_some` : $\forall (xs : \text{list var}) (p : \text{poly}),$

```
NoDup xs →
incl (vars p) xs →
is_poly p →
 $\forall s,$  sveVars xs p = Some s →
mg_u s p.
```

Proof.

```
intros xs p Hdup H H0 s H1.
apply reprod_is_mgu.
revert xs p Hdup H H0 s H1.
induction xs as [|x xs].
- intros. simpl in H1. destruct p; inversion H1.
  apply empty_reprod_unif.
```

```

- intros.
  assert ( $\exists$  qr, div_by_var x p = qr) as [[q r] Hqr]. eauto.
  simpl in H1.
  rewrite Hqr in H1.
  destruct (sveVars xs (build_poly q r)) eqn:Hs0; inversion H1.
  apply NoDup_cons_iff in Hdup as Hnin. destruct Hnin as [Hnin Hdup0].
  apply sveVars_poly_subst in Hs0 as HpsS0; eauto.
  apply IHxs in Hs0; eauto.
  apply reprod_build_subst; auto.

```

Qed.

If sveVars does not produce a substitution for the polynomial p , then the problem $p \stackrel{?}{\approx}_B 0$ is not unifiable.

Lemma sveVars_none : \forall (xs : list var) (p : poly),

```

NoDup xs  $\rightarrow$ 
incl (vars p) xs  $\rightarrow$ 
is_poly p  $\rightarrow$ 
sveVars xs p = None  $\rightarrow$ 
 $\neg$  unifiable p.

```

Proof.

```

induction xs as [|x xs].
- intros p Hdup H H0 H1. simpl in H1. destruct p; inversion H1. intro.
  unfold unifiable in H2. destruct H2. unfold unifier in H2.
  apply incl_nil in H. apply no_vars_is_ground in H; auto.
  destruct H; inversion H.
  rewrite H4 in H2.
  rewrite H5 in H2.
  rewrite substP_1 in H2.
  inversion H2. inversion H6.
- intros p Hdup H H0 H1.
  assert ( $\exists$  qr, div_by_var x p = qr) as [[q r] Hqr]. eauto.
  simpl in H1.
  rewrite Hqr in H1.
  destruct (sveVars xs (build_poly q r)) eqn:Hs0; inversion H1.
  apply NoDup_cons_iff in Hdup as Hnin. destruct Hnin as [Hnin Hdup0].
  apply IHxs in Hs0; eauto.
  unfold not, unifiable in *.
  intros.
  apply Hs0.
  destruct H2 as [s Hu].
   $\exists$  s.
  apply (div_build_unif x p); auto.

```

Qed.

Hint `Resolve NoDup_vars incl_refl`.

If `sveVars` produces a substitution σ for the polynomial p , then σ is a most general unifier of $p \stackrel{?}{\approx}_B 0$. Otherwise, $p \stackrel{?}{\approx}_B 0$ is not unifiable.

```
Lemma sveVars_correct :  $\forall$  (p : poly),  
  is_poly p  $\rightarrow$   
  match sveVars (vars p) p with  
  | Some s  $\Rightarrow$  mgu s p  
  | None  $\Rightarrow$   $\neg$  unifiable p  
  end.
```

Proof.

```
  intros.  
  destruct (sveVars (vars p) p) eqn: Hsve.  
  - apply (sveVars.some (vars p)); auto.  
  - apply (sveVars.none (vars p)); auto.
```

Qed.

If `sve` produces a substitution σ for the polynomial p , then σ is a most general unifier of $p \stackrel{?}{\approx}_B 0$. Otherwise, $p \stackrel{?}{\approx}_B 0$ is not unifiable.

```
Theorem sve_correct :  $\forall$  (p : poly),  
  is_poly p  $\rightarrow$   
  match sve p with  
  | Some s  $\Rightarrow$  mgu s p  
  | None  $\Rightarrow$   $\neg$  unifiable p  
  end.
```

Proof.

```
  intros.  
  apply sveVars_correct.  
  auto.
```

Qed.
